THE LANCET.

A Journal of British a Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pha acology, Public Health, and News.

IN WO VOLUMES ANNUALLY.

VOL. CCI.

VOL. II. FOR 1921.

ETY-NINTH YEAR.

EDITED BY

SIR SQUIRE SRIGGE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

AND

EGBERT ORLAND, B.SC., M.B. LOND., M.D. BERNE.

LONDON
RINTED BY HAZELL WATSON & NEY LD., 52, LONG ACRE, W.C. 2, AND PUBLISHED BY THE PROPRIETORS
AT THE OFFICES OF "TH ANCET," No. 423, STRAND, AND No. 1, BEDFORD STREET, STRAND.
MCMXXI.

INDEX TO VOLUME II., 1921.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Bicycle and Cycle, Child and Infant, Bronchocele, Goitre, and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, &c., &c. (Py Q) = Parliamentary Question.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index

---

A

Abbott, Dr. H. K., general infection by Cysticercus cellulosæ, 956
Abdomen, Upper, Surgery of (Dr. J. B. Deaver and Dr. A. P. C. Ashhurst), second edition, 1921 (review), 657; *Acute, Early Diagnosis of* (Mr. Z. Cope) (review), 808
Abdominal surgery, pathological and X ray examinations in (Mr. J. Sherren), 689; diseases, diagnosis of, 1220
Abercorn, Dowager Duchess, and others, National Children Adoption Association, 60
Aberdeen Sick Children's Hospital, fair in aid of funds, 311, 484
Aberdeen University, pass lists, 256, 1396; awards, 312; roll of service, 836
Abnormalities, developmental, 815
Abortion, criminal, labour after, 362, 1356; procured, position of the medical *practitioner in cases of*, 509; responsibility of doctors, 1296
Abscess of the breast (*Dr. S. C. Dyke*), 331
Accident, industrial, controversy on, 570
Achard, Ch., A. Ribot, and Leon Binet, *researches on adrenalin diabetes*, 139
Acids, dilute, rôle of, in infection, 1375
Acoustic exercises *for deaf-mutes*, 769, 1355
Acquisitive society, an, 30
Adams, Dr. D., early diagnosis and treatment of disseminated sclerosis, 291
Addison, Mr. O., *periosteal sarcoma of femur*, 1059
Addison's (Dr.) salary (Py Q), 52; tribute to, 89
Adenitis, cervical, and unhealthy tonsils (*Mr. W. G. Howarth and Dr. S. R. Gloyne*), 997
Adenoids and rickets (Dr. H. Merrall), *991*, 1079; ætiology of, 1079, 1188, 1216; (leading article), 1281, 1347
Adenoma, cystic, *of uterus*, 1003
Adenomyoma of the Fallopian tube, 297
Adolescence, Autoerotic Phenomena in (*Dr. K. Menzies*), second edition, 1921 (review), 757
Adoption *Association*, National Children, 60
Adoption, committee on (Py Q), 53
Advanced Suggestion (*Neuro-induction*) (Dr. H. Brown), second edition, 1921 (review), 707
Aerodrome workers, medical examination of (Py Q), 931
Aero-urethroscope, new, *511*
African native, the, and medical service, 883
Agglutination *for B. dysenteriæ* (Flexner), (*Dr. A. D. Gardner*), 1269
Air Force Medical Service (see Student's Guide), 169
Air pilots and physical defects (Py Q), 185; the peril of, 522; travel in France, 785
Airman's physique, 510
Airmen, nose, throat, and ear requirements of (Squad.-Leader D. Ranken), 1263
Alastrim, 1286
Alcohol, therapeutic value of, 1400
Alcoholic beverages, consumption of (Py Q), 52
Alcoholism, international aspects of, 817
Alexander, Dr. F. W., swimming bath and catarrhal otitis, 629
Alimentary disorders, the fæces in (Dr. R. Coope), 9, 89, 153, 362; canal, bacteriology of (leading article), 25; infections in chronic arthritis (Dr. N. Mutch), 1266
Alkaloids, Some Micro-Chemical Tests for (C. H. Stephenson and C. E. Parker) (review), 1329
Allbutt, Sir C., medicine in evolution (Greek medicine in Rome), 86; clinical units, 937, 1299; (leading article), 969
Allen, Dr. R. W., death of, 586
Allison, Dr. T. M., coughing cup in prevention of tuberculosis, 630
Almond, Dr. G. H., memorial to, 1397
Alpine and subalpine climatic treatment: (1) *the place of Alpine spas in medicine* (Dr. E. B. Leech), 574; (2) Switzerland and "nerves" (*Dr. S. A. K. Wilson*), 576; (3) Swiss health resorts for tuberculosis (Dr. A. N. Cox), 579
Alvarenga Prize, 879
Amblard, Dr. L. A., arterial hypertension, 760
Amœboid Movement (Prof. A. A. Schaeffer) (review), 293
American Public Health Association, jubilee, 769
Ammonia dermatitis in infants, 1288
Amœbiasis, 1291
Anæmia, aplastic (Dr. E. C. P. Williams), 71
Anæsthesia, Local (Mr. N. Black) (review), 294
Anæsthesia with nitrous oxide and oxygen under pressure (Dr. H. H. Dale and Dr. L. Hill), 326, 533; milestones in, 636; inhalation or insufflation, combined apparatus for, 660; local, in stomatology, 1123; *stovaine*, 1166
Anæsthetics, dental choice of 572; Trans-Atlantic methods of administering, 1059; parcels of, held up (Py Q), 1350
Analysis, Qualitative, Introduction to (T. W. Fresenius), *seventeenth edition*, 1921 (review), 966

ANALYTICAL RECORDS AND REPORTS.—"Asepso" soap, 968—Benzyl benzoate capsules, 1226—Biologicals, tests and remedies, 1225—Cinzano brut, 1226—"Lukmah" tonic tea, 1226—Lynd's "well-made" soap, 968—Nuvita dietetic biscuits, 400—Port, tawny, 400—Quinine ethyl carbonate (euquinine) and diquinine carbonate (aristochin), 400—"Valeda" *invalid food* and "Good as Gold" baby food, 968—Vermouth, Fratelli Corelli, Torino, 968—"Wellcome" brand anti-pneumococcus serum, type 1; "Wellcome" *brand agglutinating serum, pneumo*coccus, types 1, 2, or 3, 400—Whisky, Irish, 400—Wilbert's invalid port, 968

Anaphylatoxin, 339
Anaphylaxis, ocular reactions in, 571
Anatomical material supply of, 776
Anatomy, Regional (*Dr. T. B. Johnston*) (review), 513
Anatomy, surgical, neglect of, 778
Anderson, Dr. J., dysentery in the field, 998
Andrewes, *Dr. C. H., poisoning by* cantharadin, 651
Androgyne, Autobiography of an (review), 967
Aneurysm of right common carotid *artery*, 1059; *innominate*, ligation of innominate artery for, 1274
Angina pectoris, purulent pericarditis simulating (Dr. M. A. Cassidy and others), 559; syndrome, origin of (Sir *C. Briscoe*), 1257; new light on, 1291
Animals, living, experiments on, 523
Ankle-joint, *abduction fractures of* (Sir W. A. Lane), 697, 875
Anoxæmia in clinical neurology (leading article), 348
Anspach, Dr. B. M., Gynæcology (review), 1222
Antarctic bacteria, 88
Ante-natal factors *of life and death*, 151
Anthrax, human, in Buganda Kingdom (Dr. W. L. Peacock and *Dr. H. L. Duke*), 332; among animals in Roumania, 527
Anthrax-*infected brushes* (Py Q), 211
Anti-anaphylaxis, 1384
Antimony and emetine in *bilharzia* disease (Dr. F. G. Cawston), 1049
Antiques, collecting, 1256
Antivenereal prophylaxis, 1024
Anwyl-Davies, Dr. T., tumour of right petrous bone, 1323
Aortic regurgitation following lethargic encephalitis, 665; incompetence (Dr. *G. J. Langley*), 1209
Aphasia, the study of (Dr. S. A. K. Wilson), 1143
Apothecaries Society of London, pass lists, 1249
Appendicitis, method of approach in, 284
Appetite, effect of B-vitamin on (Dr. S. Wright), 1208
Appointments, weekly lists of, 56, 110, 161, 211, 261, 314, 369, 420, 484, 535, 587, 632, 683, 736, 783, 832, 881, 931, 986, 1036, 1084, 1138, 1195, 1301, 1398
Approved societies and medical benefit (Py Q), 1031
Arabian medicine, 298
Armenian Refugees (Lord Mayor's) Fund, 1306
Armstrong, Mr. E. A., disappearance of Oscar Gray, 828
Arm-training School at Roehampton, 96
Army Medical Service (see Student's Guide), 465; (Py Q), 485
Army statistics (Py Q), 108; hospitals, working expenses (Py Q), 311; Dental Corps, amended rates of pay, 360
Arrhythmia *in mitral and aortic disease* with extensive myocardial degeneration (*Dr. M. Davidson* and *Dr. H. G. Butterfield*), 12
Arsenical compounds, antisyphilitic action *in relation to their constitution*, 857
Arsenobenzol compounds, delayed poisoning by, 405; *treatment of syphilis*, 1111
Art Calendar, Medical, 1198
Art, medicine in, 1290
Arterial hypertension and chronic nephritis, 299; hypertension (Dr. L. A. *Amblard*), 760
Arterio-sclerosis, a study of, 31
Arteritis, unsolved mysteries of, 918
Arthritis, chronic, alimentary infections in (Dr. N. Mutch), 1266
Arthritis, *suppurative monarticular, in an* infant (Dr. A. Langwill), 1158; deformans of the hip, 1331
Arthrogenic contractures, 390
Arvedson, Dr J., Diseases Treated by Medical Gymnastics and Massage (review), 657
"*Asepso*" *soap*, 968
Ashhurst, Dr. A. P. C., and Dr. J. B. Deaver, Surgery of the Upper Abdomen, second edition, 1921 (review), 657
Assman, Dr. H., Die Röntgendiagnostik der Inneren Erkrankungen *(review)*, *563*
Association of Certificated Blind Masseurs, 1355
Association of Infant Welfare and Maternity Centres, meeting, 1326
Asthma and allied conditions, 280; bronchial, and protein sensitisation, 1174; *bronchial, and hay fever, tuber*culin treatment (Prof. Dr. W. S. Van Leeuwen and H. Varekamp), 1366
Astigmatism, correction of, 865
Asylum Doctor, Experiences of (Dr. M. *Lomax*) *(review)*, 292
Asylum patients, discharge of (Py Q), 486
Atmospheric pollution, *monthly record*, 188
Auden, Dr. G. A., problem of the head louse, 370
Aural suppuration, chronic, 1069, 1301
Auricular fibrillation, arrest of, by the use *of quinidine* (*Dr. A. W. M. Ellis and* Dr. A. E. Clark-Kennedy), 891

AUSTRALIA, CORRESPONDENCE FROM.—Folie Circulaire, 413—Women hospital residents; Mr. H. M. O'Hara, death of, 414—Australasian Medical Congress; *Charge of manslaughter*; *War Memorial*; Bubonic plague; Motor fatality, 1126

Ayurvedic Committee on drugs, 1127

B

Baby management, 1037
Baby Week Council, National, meeting, 979
Bacilli, non-lactose-fermenting (Dr. H. L. Duke), 1212
Bacillus, tubercle, in peripheral blood, 193; bulgaricus, in defence of, 570 influenza, in culture, 1232; dysenteriæ (Flexner), agglutination for (Dr. A. D. Gardner), 1269
Back, Dr. G. A., doubtful cyst of the left lung for diagnosis, 855
Backache, syphilitic, 241
Baemeister, Prof. A., Lehrbuch der Lungenkrankheiten, second edition, 1921 (review), 513
Bacterial infection and meteorology, 1235
Bacteriology, Clinical and Applied, Manual of (Prof. R. T. Hewlett), seventh edition, 1921 (review), 563
Bacteriology of the alimentary canal (leading article), 25
Baddeley, Sir J., Armenian Refugees (Lord Mayor's) Fund, 1306
Bainbridge, Dr. F. A., obituary, 980
Ball, Mr. V., incapacity for work within the meaning of the National Insurance Act, 1911, 905
Ball, Mr. W. W. R., String Figures, second edition, 1921 (review), 80

Ballance, Sir H., method of approach in appendicitis, 281
Ballantyne, Dr. J. W., Encyclopædia Medica, second edition, 1921 (review), 1115
Ballard, Mr. C. W., Elements of Vegetable Histology (review), 397
Balme, Mr. H., medical missions in China, 784
Banks, Col. S. H. O'Brien, death of, 51
Barbé, Dr. A., Examen des Aliénés (review), 707
Barber, Dr. H. W., rosacea, 308; cutaneous sensitisation and focal sepsis, 340
Barcroft, Dr. J., hæmoglobin, 46
Barrett, Sir J. W., a disclaimer, 50
Barrier Charts for Health Officers (Dr. S. H. Daukes) (review), 23
Barrington-Ward, Mr. L. E., gastric operations, 382
Barwell, Mr. H., X ray treatment of otosclerosis, 728
Bassett-Smith, Sir P. W., lemon-juice in scurvy, 321; development of hygiene, pathology, and bacteriology in the Naval Medical Service, 1321
Batten, Dr. R. D., acute macular disease, 21
Bauer, Dr. J., Vorlesungen über allgemeine Konstitutions- und Vererbungslehre (review), 1376
Baur, Prof. E., Prof. E. Fischer, and Dr. F. Lenz, Erblichkeitslehre und Rassenhygiene (review), 1329
Bayley, Dr. E., City of London Medical Book Society, 780
Bayliss, Prof. W. M., electrical action of the human heart, 49
Bayly, Mr. H. W., new penile clamp, 1226
Beattie, Prof. J. M., and Dr. W. E. C. Dickson, Text-book of General Pathology, second edition, 1921 (review), 232; the streptococci, 335; Text-book of Special Pathology, second edition, 1921 (review), 961; encephalitis lethargica, 1326
Beattie, Prof. T., visceral syphilis, 279
Beauchamp, Sir S., obituary, 1192
Beaumont, Dr. E., obituary, 1028
Bedford, Sir C., appointed honorary adviser to Secretary of State for the Colonies, 531
Bedson, Dr. S. P., blood platelets in scurvy, 336
Beerbohm, Miss C., rest and help for hospital nurses, 422
Beit Memorial Fellowships for Medical Research, awards, 1337
Belfast Royal Victoria Hospital, presentation bust, 929
Belilovsky, Dr. B., appeal from the Russian Red Cross, 308
Bell, Dr. W. B., the Sex-Complex, second edition, 1920 (review), 396; interposition operation for vaginal prolapse, 1393
Belladonna poisoning from eating rabbit (Dr. D. Firth), 901, 926; (leading article), 1065
Bellahouston Hospital report (Py Q), 1031
Benefit, additional (leading article), 613
Benham, Dr. F. L., diagnosis and treatment of diphtheria, 876; the late Col. A. B. R. Myers's autophlebotomy, 1111
Benjafield, Dr. W. B., death of, 675
Bennett, Mr. R. R., Materia Medica and Pharmacy for Medical Students, fourth edition, 1921 (review), 757
Bentley, Dr. J. R., a disclaimer, 927
Benzyl benzoate capsules, 1226
Beresford-Jones, Dr. A., pyonephrosis and ureteral calculus, 900
Beri-beri in Labrador, 1391
Bevers, Dr. E. C., abdominal tumour, 607
Bigger, Dr. J. W., Wassermann tests, 1369
Biggs, Dr. G. N., a disclaimer, 1256
Bilharzia disease, antimony and emetine in (Dr. F. G. Cawston), 1049
Bilharziasis, action of tartar emetic in, 97; treatment of (Py Q), 161
Billings, Dr. F., and Dr. B. O. Raulston, General Medicine (review), 1224
Binet, Léon, and Pierre Brocq, pathogenesis of hæmorrhagic pancreatitis, 137; Ch. Achard, and A. Ribot, researches on adrenalin diabetes, 139; and E. Lesné, Physiologie normale et pathologique du Nourrisson (review), 706
Bing, Prof. R., Lehrbuch der Nervenkrankheiten für Studierende und Praktische Aerzte, second edition, 1921 (review), 707
Binnie, Mr. J. F., Manual of Operative Surgery, eighth edition, 1921 (review), 807
Biochemistry, the growth of, 723; the thread of, 1382
Biochemistry (Prof. B. Moore) (review), 655; Practical Physiological Chemistry (Drs. J. A. and T. H. Milroy), third edition, 1921 (review), 1328; Dictionnaire de Biologie Physiciste (Albert and Alexandre Mary) (review), 1328; Some Micro-Chemical Tests for Alkaloids (C. H. Stephenson and C. E. Parker) (review), 1329
Biological Chemistry (Dr. H. E. Roaf) (review), 1223; Chemistry, Practical (G. B. and P. Thomas) (review), 1224
Biological station, new, in the Austrian Alps, 1243; products, licensed, in U.S.A., 1255
Biologicals, tests and remedies, 1225
Biology and medicine, history of, course of lectures on, 780
Biophysics, Introduction to (Dr. D. Burns) (review), 1114
Birmingham General Hospital, report, 735, 1397; doctors and the panel system, 780; Women's Hospital, jubilee celebration, 831; Cripples' Union New Convalescent School, opening ceremony, 874; Nerve Hospital, report, 1356
Birth, control, 75, 179; control, constructive, 481, 510, 908; seven at, 1037; live, definition of, 1073; control and welfare centre, combined, 1198
Births and Deaths, the Law of (Mr. C. E. Pell) (review), 610
Births, marriages, and deaths, weekly lists of, 56, 111, 161, 211, 261, 315, 369, 420, 484, 536, 588, 632, 684, 737, 784, 833, 882, 932, 986, 1036, 1085, 1138, 1196, 1252, 1304, 1352, 1398
Black, Mr. N., Local Anæsthesia (review), 294
"Black peril" in U.S.A., 635
Blackhall-Morison, Dr. A., inquiry into Insurance Acts, 827
Blackman, Dr. V. H., plant diseases and their relation to diseases in man, 935
Bladder drainage and closure, new devices, 346; intraperitoneal rupture of (Dr. Dorothy Chattaway), 754; diverticulum of, 770; lamp, new, 968
Bligh, Dr. M., ketosis in children, 1220
Blind population of India (Py Q), 107; and paralysed ex-Service men (Py Q), 160; girls, college for, 214; welfare of, 306; L.C.C. and care of, 863; in Ross and Cromarty, provision for, 929; London, Central Council for, 973; and smoking, 1088; children, swimming facilities for, 1190
Blinded, re-education of (Sir A. Lawson), 514
Blindness, causes and prevention, 510
Blood, peripheral, tubercle bacillus in, 193; diseases in children, 391; diseases of, radiation treatment, 393; counts to indicate efficiency of X ray and radium protection, 393; sugar regulations, 406; mononuclear leucocytes of, action of radium and X rays upon, 962
Blood, Practical Chemical Analysis of (Prof. V. C. Myers) (review), 911; Diseases, Polycythæmia, Erythrocytosis, and Erythræmia (Vaquez-Osler Disease) (Dr. F. P. Weber) (review), 1115
Blood, reaction of, regulation of, 572; reaction of (Dr. C. A. L. Evans), 867; donors, 1123, 1247; platelets, association of typhus virus with, 1292; transfusion for burn shock, 1335
Bolk, Prof. L., part played by the endocrine glands in the evolution of man, 588
Bolton, Dr. Elizabeth, sterility, 1325
Bonar, Mr. T. G. D., gastric function before and after gastro-jejunostomy, 952
Bond, Dr. C. H., psychological medicine, 319
Bone and joint tubercle, domiciliary treatment (Dr. W. C. Rivers), 1155
Bone-grafting, 286
Bonuses, treatment, conference on, (Py Q), 161
Boobbyer, Dr. P., small-pox in Nottingham, 254
Books, early, on medicine and anatomy, 213; medical, for lay readers, 243
Books, &c., received, 60
Bookless, Mr. J. S., grey mass in vitreous, 904
Borderland cases, diagnosis and treatment, 288
Bose, Dr. G., Concept of Repression (review), 564
Botany, an Introduction to the Structure and Reproduction of Plants (F. E. Fritch and E. J. Salisbury) (review), 135; for Medical and Pharmaceutical Students, Text-book of (Dr. J. Small) (review), 184
Bottle-fed baby, 740
Bousfield, Dr. P., objective study of neurosis, 533
Bowers, Mr. E. F., and Mr. T. J. Ryan, Teeth and Health (review), 79
Boy, the, in Industry and Leisure (Rev. R. R. Hyde) (review), 809
Boycott, Prof. A. E., teaching of pathology in America, 773
Bradshaw lecture on subtropical esculents (Dr. M. C. Grabham), 1357
Brain lesion, action of pilocarpine in, 405
Bramwell, Dr. E., encephalitis lethargica, 281
Breast, abscess of (Dr. S. C. Dyke), 331
Brett, Dr. P. C., and Dr. J. C. Spence, lævulose as a test for hepatic inefficiency, 1362
Brighton water-supply, 936
Bright's Disease (Prof. L. Lichtwitz) (review), 656
Briscoe, Sir C., anginal syndrome, origin of, 1257
Bristol, hospital conditions in, 206; Medical Committee, 207; payments by hospital patients, 1033; Maternity Hospital, opening, 1100; Eye Hospital, meeting, 1294
Bristol Medico-Chirurgical Society (see Medical Societies)
Bristol University, pass-list, 156; appeal, 255, 1033; retirement of Sir I. Owen from the Vice-Chancellorship, to be succeeded by Principal Loveday, 1250
British Association at Edinburgh (leading article), 567—Aims and boundaries of physiology; Kidney deficiency tests; Vitamins in relation to public health, 623—Presentation to Sir E. S. Schafer, 624—Oxidations and oxidative mechanisms in living tissues; Physiology of heavy muscular work; Physiological cost of muscular work; Economy of human effort in industry, 670
British Columbia, Drugless Healing and Chiropractic Bills, 870
British Congress of Obstetrics and Gynæcology (see Medical Societies)
British Dentists' Hospital, report, 661
British Hospitals Association, meeting, 106
British Medical Association (leading article), 189

BRITISH MEDICAL ASSOCIATION AT NEWCASTLE-ON-TYNE (ANNUAL MEETING).—Representatives of the press; Future arrangements; State visit from the Lord Mayor; The year's finance, 196—"British Medical Journal"; Professional secrecy; Proposed Central Medical Committee, 197—Federation of overseas branches; Affiliation with medical and non-medical bodies; The postal vote, 198—Admission of non-members to sectional meetings; Subscription to the Association; Student class of membership, 245—Expenses of representatives; State reward for scientific research; Voluntary hospital principle; Municipal and State grants;

Formation of Medical Staff Fund; Staff Fund and voluntary principle, 246—Paying patients in Poor-law hospitals; Hospital provident scheme for London; Salaries of non-professorial teaching staff; Medico-Political Committee; Whole-time medical officers and private practice, 247—Fee for *notification of infectious disease*; Report on maternity and child welfare; Election of officers; *Annual general* meeting, 248

Medicine.—Visceral syphilis, 279—Asthma and allied conditions, 280—Encephalitis lethargica, 281

Surgery.—Acute pleural empyema, 282—Method of approach in appendicitis; Intussusception; Compound fracture of the thigh and leg; Fracture of the tibia and fibula, 284—Theory and *method in extension of the thigh*, 285—*Bone grafting; Diagnosis and treatment of injuries of the intestines*, 286—Treatment of injured intestine, 287—Demonstrations, 288

Neurology and Psychiatry.—Diagnosis and treatment of borderland cases, 288—*Nervous diathesis and the blood*; Some points in the management and treatment of paraplegia; Physiology of symptom production, 290—Epilepsy *from* the psychological standpoint; Early diagnosis and treatment of *disseminated sclerosis*, 291

Pathology and Bacteriology.—Hæmochromatosis, 331—*Relation of carcinoma to infection*, 335—Blood platelets in scurvy; Pathology of gastric and duodenal ulcer; Experimental tar cancer in mice; *Renal function tests*, 336; Demonstrations, 337

Pathological Museum.—Specimens and exhibits, 337

Physiology, Pharmacology, Therapeutics, and Dietetics.—Various uses of the "hot wire," 338—*Ætiology and treatment* of varicose ulcers; anaphylatoxin; Certain electrical sign of the *human body*; Poison organs and venoms of poisonous fishes; Physiology *of oral hygiene*, 339

Dermatology.—Association of skin tuberculosis with *visceral* and other tuberculous manifestations, 339—Cutaneous sensitisation and *focal sepsis*, 340—Skin diseases in pensioners, 341

Urology.—Diagnosis and treatment of cystitis; *Contusions of the kidney*, 342; Open operation for removal of the prostate, 343

Orthopædics and Diseases of Children.—Early diagnosis and treatment of anterior poliomyelitis, 389—Arthrogenic *contractures*; *Birth paralysis*, 390—Blood diseases in children; Pre-natal *treatment of syphilis*; hypertrophic pyloric stenosis; Tuberculosis of bone *in children*, 391—Milk control and tuberculosis, 392

Ambulance and Red Cross.—*Claims of* first-aid to be regarded as a special branch of practical *surgery*, 392—X ray motor ambulance wagon service, 393

Electro-Therapeutics and Radiology.—Radiation *in treatment of diseases of* the blood; Use of blood counts to indicate the efficiency of X ray and radium protection; X ray diagnosis, 393—Surgical diathermy, 394

Exhibition.—Surgical instruments, drugs, *foods*, and other products of medical interest, 394

Preventive Medicine with Industrial Diseases.—Effect of health legislation on the health of the people, 500—*Importance of* industrial medicine to the community, 501

Obstetrics and Gynæcology.—Rôle of Cæsarean section in midwifery, 502—*Treatment* of advanced malignant disease of the cervix, 504—Neurasthenic element in gynæcology, *505*—Curettage and the treatment of uterine hæmorrhage, 507—Position *of the medical* practitioner in cases of procured abortion, 509

Hunterian Lecture

[ABRIDGED]

ON

INJURIES OF THE DIAPHRAGM.

WITH SPECIAL REFERENCE TO ABDOMINO-THORACIC WOUNDS.*

Delivered before the Royal College of Surgeons of England

By C. W. GORDON BRYAN, *M.C.*, F.R.C.S. Eng.,

SURGEON TO OUT-PATIENTS (ADDITIONAL) AND ORTHOPÆDIC SURGEON, ST. MARY'S HOSPITAL; HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

INJURIES of the diaphragm are of consequence partly on account of the important physiological functions in which the muscle is engaged, partly because of its close anatomical relationship to important viscera of the abdomen and thorax. The effects of such injuries have been met with much more commonly in recent years, and the reasons for this are clear; street accidents, so frequent in these days of motor transport, are responsible for most of the cases seen in civil life, and the great war, and the numerous smaller wars that have succeeded it, have brought a very large number of cases under the care of military surgeons. As a weapon of revenge the popularity of the dagger has waned, but the revolver has a prominent place in methods of reprisal, and the diaphragm often suffers.

In the cases usually met with in civil surgery the muscle is ruptured as a result of crushing violence, whereas injuries of the diaphragm seen in military surgery are commonly produced by an open wound. Each of these types of injury produces consequences of surgical importance at two stages—an early stage in which serious symptoms follow immediately after the injury, and a late stage where the patient suffers from certain special complications months or years afterwards.

I propose, then, to consider the subject of this lecture in two parts, dealing first with the early effects, and afterwards with the late effects of injuries of the diaphragm.

EARLY EFFECTS OF INJURIES OF THE DIAPHRAGM.

Injuries Without an External Wound.

When the diaphragm is injured by severe external violence in the nature of a crush, it may be ruptured by a stretching and bursting mechanism, or it may be torn by the sharp end of a fractured rib; such cases are of two types, according to whether the vault or one of the crura of the muscle is implicated.

Rupture of the Vault of the Diaphragm.

This is the commoner lesion, and is usually due to a person being run over. It occurs most frequently in children and adolescents, because their thoracic skeleton is elastic and can be compressed to a considerable degree without fracture. The mechanism of simple rupture of the diaphragm is of interest, and in this connexion I have had convincing personal proof of the amount of compression and displacement that the thoracic wall and the upper abdominal viscera can withstand without harm, for at the age of 18 it was my fortune to be run over by a motor-bus, weighing about two tons and containing six people, the back wheel passing over the right hypochondrium and lower chest, across the sternum and the left shoulder; after the accident no lesion was discoverable until the right side of the chest-wall fell in three days later, as a result of the separation of the attachments of the right costal cartilages. Two years ago I saw a precisely similar condition in a girl of 3 years, run over by a car which passed obliquely across the left hypochondrium and right chest, and caused no apparent injury beyond costo-chondral dislocations.

Such escapes are to be considered fortunate, for it is by similar violence that rupture of the diaphragm is caused. A tear of the right side is very uncommon owing to its relation to the liver, which from its comparative immobility has to bear the brunt of a compression injury of this region. I have seen a case of severe reactionary hæmorrhage from the liver into the pleural cavity through an opening in this part of the muscle. On the other hand, the mobility and elasticity of the viscera on the left side enable them to act as a sort of air-cushion and transmit the force to the stretched diaphragm, and it is ruptured; the tear usually occurs in the posterior part of the muscle, and sometimes extends into its œsophageal opening. The symptoms at first are those of shock, dyspnœa, and disordered action of the heart. The breathing presents certain typical characters; its rate is little altered, but it is almost entirely thoracic in type, with a catch at the end of inspiration (sometimes definite spasm or hiccough); painful and repeated cough may occur, and the lips are blue. The pulse is rapid and irregular. After about 24 hours the patient may recover from shock, and diaphragmatic breathing be restored by the tear becoming plugged by omentum. In several instances the patients have appeared remarkably free from symptoms after the first two days. The early development of a hernia of the stomach into the left pleural cavity, usually accompanied by omentum and transverse colon, gives rise to vomiting and other signs of obstruction, but without distension. Dyspnœa and tachycardia recur, and severe pain is present, in the abdomen and often in the neck or shoulder. The chest signs resemble those of hydro-pneumothorax. The hernia may reduce itself and recur later, it may become chronic, or it may lead to early death from shock and obstruction.

The difficulties of diagnosis in these cases are well known, and X ray examination may be fallacious, for it is often quite difficult to persuade an opaque meal to enter the supra-diaphragmatic pouch of the stomach. In war surgery it was first pointed out by Lockwood that the cardiac and respiratory embarrassment of wounds of the diaphragm was very similar to that of open pneumothorax, and that the condition of patients improved as soon as the communication between thorax and abdomen was closed. It is this consideration that makes early operation of importance, also in cases of simple rupture of the muscle; the rapidity of the pulse, being due partly to mechanical causes, is no criterion of the degree of shock.

A case admitted to St. Mary's Hospital in 1917 illustrates the early effects of simple rupture of the diaphragm. The paitent, a girl of 5, was run over by a taxi-cab; she vomited at once, and on two occasions after admission; she was in a state of severe shock and lay on her left side. After 48 hours her condition was good, and she was taking ordinary food; on the sixth day, however, she began to complain of severe pain in the abdomen and in the back of the neck, and any food taken was vomited at once; next day there were signs of air and fluid in the left chest, and the heart was displaced to the right. The symptoms abated, only to recur three days later; diaphragmatic hernia of the stomach was diagnosed by the surgeon, but X rays showed that bismuth passed normally below the diaphragm, and the radiographer considered the case one of hydro-pneumothorax. Exploratory operation was precluded by the collapsed state of the child and she died on the following day. Autopsy showed a tear of the diaphragm through which the whole of the stomach, the omentum, and part of the transverse colon had passed. The alternating periods of severe illness and apparently normal health made the case one of great difficulty: the hernia evidently had reduced itself after its first appearance, only to recur with fatal result.

Rupture of the Crus of the Diaphragm.

This must be an uncommon injury, of which I have seen one example, in association with fracture of the spine. The diaphragm injury was of clinical importance, as it gave rise to great respiratory distress and intraperitoneal hæmorrhage, which simulated rupture of a viscus.

---

* Published in full, with illustrations and bibliography, in the current number of the British Journal of Surgery.

The patient, a man of 40, fell over 30 feet on to pavement; admitted at once to St. Mary's Hospital, he suffered from severe shock, and a compression fracture of the eleventh and twelfth dorsal vertebræ and fracture of the pelvis were present; signs of intrathecal bleeding developed later. Five hours after the accident the breathing was shallow, of thoracic type, with a catch at inspiration; the right *upper rectus showed a small area of rigidity. A diagnosis* of injury in the neighbourhood of the crura of the diaphragm was made, with possible rupture of the duodenum, and the abdomen was explored by a left paramedian incision, carried outwards below through the left rectus. There was a rupture of the internal part of the left crus of the diaphragm, and from this and from the œsophageal branches of the coronary vein blood was escaping through a tear in the overlying peritoneum; the bleeding was arrested, the distended stomach was washed out, and the abdomen was closed. After suffering from hiccough for a few days, the man made a complete recovery from all the injuries.

Simple Laceration of the Diaphragm by a Fractured Rib.

Penetration of the diaphragm by a rib which has sustained a simple fracture usually results from direct violence to the ninth or tenth rib, and the bone may also lacerate the spleen or liver. It is, I think, not commonly realised that this is the mode of injury of some cases classed as rupture of the spleen, and that the severity of the symptoms is partially due to hæmorrhage, and partially also to the handicap that injury of the diaphragm places on heart and respiration. The chances of recovery are improved by closing the opening in the muscle.

In dealing with a bleeding spleen through an abdominal-wall incision, considerable manipulation may be necessary, and the difficulty of exposure makes anything short of splenectomy almost impossible. Since it is known that the old fear of opening the pleura was an unnecessary one, the advantages of approaching certain injuries of the spleen through the chest wall are definite, especially injuries due to rib fracture. In the absence of fracture the tenth rib may be resected and the unopened pleura pushed aside; if a fracture is present, the broken rib is removed, the openings in pleura and diaphragm are enlarged, and their edges are sutured together to close the pleural sac. The exposure of the spleen thus obtained allows of the damaged portion being sutured or resected, procedures of far less severity then splenectomy; even if removal of the spleen is necessary, the manipulation of the pedicle, so productive of shock, can be carried out more gently than through an abdominal-wall incision.

Dealing with injury of abdominal viscera by transthoracic laparotomy is not new, for in 1912 Sauerbruch[1] described three successful operations, carried out under differential pressure.

It appears then that simple rupture of the diaphragm causes symptoms which may be easily overlooked or attributed to shock and *hæmorrhage*; such rupture may be associated with bleeding from spleen or liver, and in operating for these conditions the diaphragm should be examined, and sutured if torn, in order to relieve the immediate embarrassment of heart and lungs and to prevent diaphragmatic hernia.

Penetrating Wounds of the Diaphragm; Abdomino-thoracic Wounds.

While I realise that the partial cessation of war makes this part of my lecture to some extent a matter of historical interest, at least it is recent history; in spite of all hopes wars have not finally ceased, and it is reasonable to expect that the opportunity will be forced on some of us to return reluctantly to military surgery: moreover, in civil war and in peace, penetrating wounds of the diaphragm do occur from time to time. Such wounds had a very high mortality in the great war: the severity of those seen at casualty ing stations made one realise how many deaths on the battlefield and in field ambulances must have resulted from wounds implicating the diaphragm.

As is well known, in 1915 it was established that the correct treatment of wounds of the abdomen, with the exception of some in its upper part, was early operation. Severe wounds, involving thorax as well as abdomen, were judged to be outside the range of active surgery. At this earlier period the treatment of wounds passing through the diaphragm was little more advanced than at the time of Waterloo; Guthrie, in his book dealing with the war surgery of that period and of the Crimea, gave details of a series of cases. He called attention to the peculiarity of the breathing—"dyspnœa with a peculiar sort of jerk or spasm," and to the important symptom of pain on the top of the shoulder with loss of power of the arm. However, the early operative treatment of chest wounds was developed, and soon extended to the more severe abdomino-thoracic cases. These wounds were very common, owing to the large target that the sloping surfaces of the diaphragm offer to missiles, from whichever direction they approach. It was soon apparent that the results of operations on the trunk, especially in tented hospitals, were more disappointing in winter than in summer; and at all times excessive cigarette-smoking, often right up to the hour of operation, increased the risks of chest surgery, while constipation made abdominal wounds in soldiers specially difficult; the coexistence of both factors made abdomino-thoracic surgery particularly dangerous. The wounds were usually due to bullets or fragments of shell or bomb; in fact during my service as a surgeon for more than four years in France and Belgium I never met with a bayonet wound of the diaphragm. Of a series of 50 cases, 16 were due to bullets, 34 to shell or bomb; the notes are unfortunately only a part of those that I made during the last two and a half years of the war, for some were lost during the rapid travelling that was forced upon us in March, 1918.

Prognosis.—In shell wounds the prognosis depended partly on the size of the fragment; a man rarely reached England with a large fragment retained in thorax or abdomen; such cases either died or had the missiles extracted in France. Except at times when the numbers of wounded necessitated the exclusion of cases of bad prognosis, I thought it right to operate on most desperate cases, not only in hope of occasional successes, but also because a policy of despair is bad for morale.

The most serious element of a wound traversing the diaphragm may be (1) the actual opening in the muscle; (2) the injury of thoracic organs; (3) the abdominal lesions; (4) severe injuries of abdominal and thoracic viscera in the same patient. The actual opening handicaps circulation and respiration, it allows prolapse of abdominal organs into the thorax, and it enables infection to escape from below to the pleura, and in the opposite direction. The thoracic injuries interfere with respiration from collapse of the lung, hæmothorax, and pneumothorax; and they may endanger life by loss of blood, sepsis, and injury of the heart. The dangers of the abdominal lesions are hæmorrhage, sepsis, intestinal obstruction, and interference with processes of metabolism, such as may result from a wound of the liver.

The *diagnosis* of injury of the diaphragm can usually be settled in through-and-through wounds of the body by estimation of the line that the missile has taken; if it is retained, its localisation by X rays and the character of the breathing are the indications of most value. The patients usually arrived at the clearing station in a state of shock and exhaustion, and in most instances resuscitation by rest and warmth was necessary; at this stage estimation of the blood pressure gave a more useful indication of the patient's condition than the pulse-rate; the slow pulse of men wounded in the liver is apt to be deceptive.

Treatment.—The primary objects of early operation in chest wounds are the prevention of sepsis and the closure of an open wound of the pleura, and the same considerations apply when the abdomen also is involved, but here the further complication of serious hæmorrhage is more often present; every hour of waiting diminishes the chances of success. Clean bullet wounds and small through-and-through shell wounds often did well without operation, hæmothorax being dealt with by repeated aspirations. In some of the lighter cases such simple operations as excision and suture of the wounds of the thoracic wall and the diaphragm were performed, but experience of sepsis of lung and pleura, extra-peritoneal cellulitis, and abscess of the liver convinced me that thorough cleansing of the whole track was the safer policy. Radical treatment is especially necessary in wounds due to large projectiles, on account of the dangers of indriven cloth, lacerated muscle, comminuted bone, and "sucking" or "leaking" condition of the thorax.

---

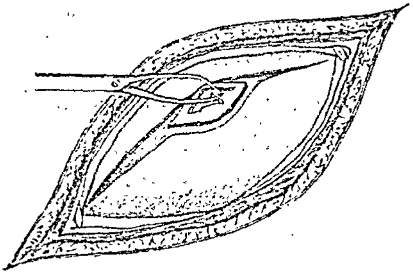
[1] Trans. German Congr. of Surg., 1912, i., 142.

The severity of the patient's general condition is no bar to active surgery, for to a man who appears very ill soon after the receipt of a wound of the diaphragm operation usually holds out the only hope of recovery, and it is impossible to estimate to what degree his symptoms are due to hæmorrhage, to mechanical interference with thoracic viscera, and to hernia of abdominal contents, all of which can be corrected by early operation.

Operative Methods.—Two general methods of operation have been employed by different surgeons:—

1. Operation through an abdominal incision, a separate incision of the thoracic wall being made, if necessary, for dealing with intra-thoracic injuries.

FIG. 1.



Excision and enlargement of wound of diaphragm.

2. An incision through the lower part of the chest wall, carried forwards and downwards into the abdominal wall in certain circumstances. It has been found possible to deal with most of the abdomino-thoracic wounds by this type of operation, and I give a general description of its stages.

(*a*) If there is a wound of the lower part of the thorax, it is excised with injured muscle, bone and pleura, in one piece.

(*b*) Any lesion of the lung is then dealt with, pieces of metal, bone, and cloth being removed, and the contaminated portion of lung is best excised and sutured.

(*c*) The pleura is then cleansed, in slight cases by swabbing, in severe ones by eusol, run in through a tube and siphoned off; swabbing has advantages but causes a great deal of shock if it is prolonged.

(*d*) The wound of the diaphragm is excised, and enlarged if necessary (Fig. 1); its edge is then securely sutured to the intercostal muscles, closing the pleural cavity. Speed in the above stages of the operation is very important.

(*e*) The abdominal viscera are examined and repaired (Fig. 2), the incision being carried downwards and forwards through abdominal wall and costal margin if necessary.

(*f*) The wound is sutured in layers, drainage of the abdomen being established in certain cases.

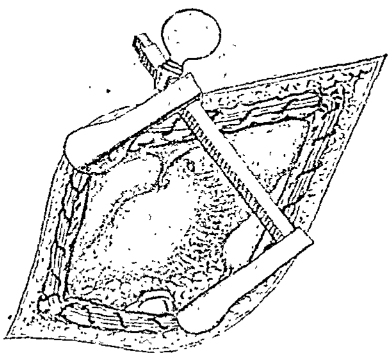
An operation of this nature, modified to suit the needs of individual cases, provides good access to every part of the lung, and in this way I have dealt with wounds of the spleen, stomach, liver, colon, kidney, and small intestine. Suturing the diaphragm to the chest wall allows the abdominal part of the operation to be done with the pleural sac closed, and it is more secure than independent suture of each opening.

In minimising the shock of so severe an operation, the method of anæsthesia is most important. Paravertebral nerve-blocking, with gas-oxygen, was employed in most of the cases; if gas was unobtainable just sufficient chloroform or ether to keep the patient in light sleep was given. Transfusion of blood was responsible for many successes. It was given towards the end of the operation; I think this is less wasteful, and perhaps more useful, than to give it as a preliminary measure; for one thing, the patient operated on before transfusion needs less anæsthetic. Oxygen was given during and for several hours after the operation, the only stimulant that is not valueless or harmful, and rectal and subcutaneous saline, up to 20 pints in 24 hours, was used as a routine.

Varieties of Wounds of the Diaphragm.

To make an elaborate classification would appear to serve no useful purpose, but the following aspects may be borne in mind: 1. The part affected, whether the central tendon, the right or left vault, or the margin. 2. The relation of the direction of the missile to the muscle; parallel to its surface, causing injury by indriven fragments of rib, or producing a gutter-wound; oblique, perforating the muscle; missiles whose direction nearly corresponds to the long axis of the trunk. 3. Complications of sepsis and hæmorrhage. 4. Associated injury of liver, spleen, pancreas, kidney, stomach, colon, jejunum, omentum, or lung. 5. Prolapse of abdominal contents into the thorax.

FIG. 2.



Diaphragm sutured to the intercostal muscles, closing pleural sac, and exposing abdominal viscera.

Most wounds of the central tendon involve the heart; such cases rarely reached the clearing stations, and I never saw one that was not moribund on arrival. Contour wounds, more or less in the line of the margin of the thorax, may cause severe injury to the edge of the diaphragm without involvement of the pleura. Wounds of this type, even when the peritoneum is uninjured, repay early excision en masse of the wound, fractured cartilages and ribs, and suture of diaphragm and chest wall; this prevents suppuration and the disability that results from a large mass of scar tissue in this situation. In wounds at a higher level the missile might remain above the diaphragm, but a perforation be caused by fractured rib driven through the muscle.

CASE 31.—Wound of diaphragm and liver by fractured rib. Wounded by shell 9.30 A.M., May 16th, 1918. Missile passed through the right arm, dividing the brachial artery, and entered the chest, fracturing the sixth and seventh ribs. Operation six hours later: brachial artery ligatured; thoracic wound, with fractured part of ribs, excised, projectile removed from pleural cavity, which was then cleaned and its upper part closed by suture of diaphragm to chest wall; hole in diaphragm, due to fractured end of seventh rib, sutured: wound closed, with rubber-tissue drain to costo-phrenic recess. Aseptic healing. Evacuated to base on ninth day with no chest symptoms.

Similar wounds fracturing several of the lower ribs were frequently responsible for severe injury of pleura, diaphragm, and under-lying viscera by indriven bone, again the missile itself not penetrating; wounds of this type were commonly seen on the right side, left-sided ones being more rapidly fatal.

CASE 26.—Contour wound causing indriven fractures of five ribs and severe laceration of diaphragm and liver with prolapse of omentum. Wounded by shell 11 A.M., March 24th, 1918; extensive open wound of right lower thorax, prolapsed omentum. Ten hours later pulse 72, poor volume: operation at once, excision of the large mass of damaged tissue, with five fractured ribs and lacerated area of diaphragm, pleura cleansed and closed; lacerated liver resected and sutured. prolapsed omentum removed; peritoneal cavity closed off by suture, with gauze pack to liver. The patient had been wounded in front of Arras on a day of the greatest anxiety to the British Army; he had to be sent to the base, in good condition, on the following day. I was unable to trace his subsequent history, but his chances were small.

On the left side wounds of this nature may cause injury of stomach or spleen, or allow the escape of abdominal viscera into the pleura.

CASE 10.—Contour wound with prolapse of stomach and omentum into pleura. Wounded by shell, and admitted same day with large "sucking" wound fracturing eighth left rib; extreme dyspnœa, pulse 130. Operation: wound and shattered rib excised, stomach and omentum prolapsed through large hole in diaphragm; stomach reduced and omentum removed; inner margin of diaphragm opening sutured to intercostals, and wound closed with subcutaneous drain. At close of operation breathing and pulse had much improved. Third day, pulse 110, condition fairly good, but signs of extensive bronchitis in both lungs; death from broncho-pneumonia on fourth day. The man was fat and 40, and this and the cold December weather were unfavourable factors.

Missiles whose line is nearly parallel to the surface of the diaphragm may cause long cuts in the muscle, sometimes not dividing the peritoneum. This type would allow the subsequent development of diaphragmatic hernia with a peritoneal sac.

CASE 1.—Gutter wound of diaphragm, missile retained in costo-phrenic recess. Wounded by shell. On admission a lacerated wound related to ninth left rib; left abdomen rigid. left thorax immobile. Operation: wound and fractured rib excised. Examination showed a wound of the diaphragm, 2 inches long, 1 inch wide, running from before backwards. Incision prolonged forwards and downwards; examination of under aspect of diaphragm showed its peritoneum intact. Returning to the pleural cavity, a piece of shell and some cloth were removed from costo-phrenic recess. Diaphragm and parietes sutured with subcutaneous drain. Wound healed by first intention, and patient was sent to the base, quite fit, ten days later.

On the right side through-and-through bullet wounds from the hypochondrium to the eighth, ninth, or tenth intercostal space usually do not need operation, in the absence of bleeding from the liver, which is unusual. If, however, by a wound of this type a rib has been fractured, there is distinctly more risk of infection; at the first possible opportunity, therefore, the wounded skin. muscle. pleura, and fractured rib are excised en masse, and primary suture without drainage is carried out.

Through-and-through shell wounds due to small fragments of shell were treated on the same lines, but infection of the pleura or liver and subphrenic abscess occurred more commonly than in bullet wounds of this region. In shell wounds primary operations for the arrest of hæmorrhage were frequently necessary, severe bleeding from the liver being usually caused by large fragments.

CASE 10.—Large bleeding wound of liver, with open pneumothorax. Wounded at 2 P.M. by bomb, causing large two inches outside right nipple, which being of the variety was sutured at the field ambulance. sile could be felt among muscles related to ninth Operation (0.30 P.M.): entrance of sixth intercostal space excised and enlarged; much blood and some fragments of liver, lying free in pleural sac, removed; large wound of diaphragm excised, and pleural cavity closed; detached pieces of liver removed from subphrenic space, large gutter wound of liver bleeding; liver wound cleansed, light gauze pack, suture of parietes. Projectile and surrounding tissues excised, opening pleura at ninth interspace; sutured without drainage. Next day, temperature 105° F. Third day, temperature 102°, pulse 100, much bile and old blood discharging. Twelfth day, patient quite fit, temperature having been normal for some days; posterior wound healed without sepsis, anterior wound clean and closed by healthy granulation; sent to base.

A common variety of wound was where a small fragment of shell had passed through the lower part of the thorax into the liver and was retained; at first I thought these cases could be best treated conservatively, but experience showed that cloth was often carried in and caused acute suppuration of the liver in some cases.

CASE 7.—Acute abscess of liver around two pieces of shell. Wounded by projectile fracturing anterior part of right eighth rib. Operation (same day): wounds of chest wall and of diaphragm excised and sutured independently without drainage. Sixth day wound healed, aseptic; fever, tenderness of liver; X rays showed two foreign bodies in left lobe of liver. On the seventh day I was asked to operate, the man being intensely toxæmic. Operation: exposure by the method of Auvray, foul-smelling subphrenic abscess opened, wound entering upper and outer aspect of liver traced through long track to abscess, containing two pieces of shell, situated in posterior part of left lobe; abscess drained, wound sutured. Death from toxæmia next day.

As well as infection of the liver, fragments of shell retained in this organ often caused infection of the pleura and the subphrenic space, while secondary hæmorrhage into the pleura and biliary fistula were less frequent complications. Experience of such complications convinced me that it was safer to remove by primary operation every fragment of shell, bone, or cloth from this viscus. The operation is quick and simple; the thoracic wound is excised, the opening in the diaphragm is identified, and a cone of the muscle is pulled well out, so as to close off the pleural sac; the edges of the diaphragm wound are then excised and the muscle is sutured to the intercostals; the track in the liver is followed up and is cleaned with Volkmann's spoon and gauze, after the missile and all cloth have been extracted; the wound of the chest wall is closed with a wick of gauze or rubber tissue in the liver track. In allowing drainage this method is safer than to close the openings in diaphragm and chest wall independently. Severe primary hæmorrhage from the liver into the pleura was not uncommon, but similar secondary hæmorrhage was less often seen.

CASE 21.—Infection of pleura by *B. perfringens*, severe secondary hæmorrhage from wound of liver, due to small fragment of shell which was retained. Wounded 2 P.M., Dec. 27th, in posterior part of tenth right interspace; severe collapse, rigidity and tenderness of hypochondrium; X rays showed small foreign body in liver, six inches deep. Operation (10.30 P.M.): wound excised, much blood removed from pleura, chest wall sutured. Jan. 6th: leaking of foul, bloody fluid from wound, *B. perfringens* identified; stitches removed, pleura drained. Jan. 10th, severe secondary hæmorrhage filling pleura and escaping externally; ninth rib excised, pleura cleared of blood and closed by diaphragm-intercostal suture; light pack of bleeding liver track; 800 c.cm. blood transfusion. The patient died of collapse and toxæmia. A thorough primary operation might have been expected to give a better result.

In all cases of wound of the liver. however slight the injury might appear, there is a risk of the development of a train of symptoms of extremely acute onset, followed by death in a few hours; a patient who is apparently doing well, with normal pulse and temperature, suddenly about the fourth day becomes intensely collapsed, and the pulse is not palpable; there may be acute delirium, and the temperature runs up to 105° or more; death takes place in a few hours. Post-mortem examination in several cases showed no suppuration or hæmorrhage; on section the whole liver was pale, except for a bile-stained zone around the wound. The clinical condition of these cases closely resembled that seen in delayed anæsthetic poisoning, and appeared due rather to toxæmia from destruction of liver tissue than to infection.

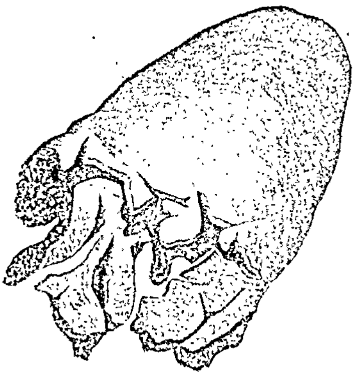
Injury of the lung by a missile which passes through the thorax before entering the abdomen is a serious complication, but needs no special consideration here; it suffices to say that any special treatment for the lung should be completed before the abdominal part of the wound is dealt with. Implication of both lungs in a wound which traverses the diaphragm usually causes death; in one case of this nature I had to operate for hæmorrhage from lung and kidney.

CASE 32.—Wounded by bullet entering sixth right interspace, exit posterior aspect left chest; severe hæmorrhage from wound and hæmoptysis. Operation within 12 hours. Exit wound and four fractured ribs excised; lung, adherent to pleura and bleeding freely, sutured; left kidney, extensively lacerated, excised; diaphragm and chest wall sutured; patient died the same day.

Wounds that traverse the diaphragm and then enter the lung are more serious as a rule than those passing from above downwards; of this class the most favourable are those that enter the lower part of the chest wall, pass through the diaphragm in two places, and then enter the lung. The passage of a projectile into the thorax, after traversing the intestine, nearly always caused death; I know of no case that recovered if the missile wounded the lung after passing through the gut. Wounds of the colon involving the pleura were specially difficult to deal with, and the danger of death from infection of pleura or retroperitoneal cellulitis was very great; to diminish the risk of the latter complication I adopted the expedient of making an oblique incision and leaving unsutured all the layers of the abdominal wall, except the peritoneum; such wounds do not gape if the patient is kept sitting up without intermission.

Thanks to excellent nursing the following case of shell wound of right kidney, hepatic flexure of colon, diaphragm, and pleura, with fracture of rib, recovered in spite of the pleura, peritoneum, and perinephric fat being severely contaminated with colon contents. (Fig. 3.)

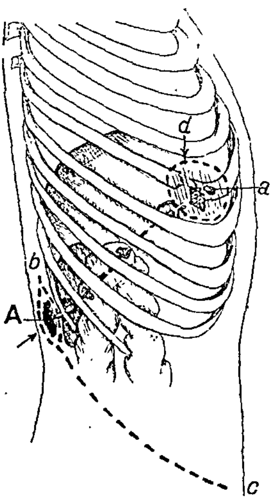
FIG. 5.



CASE 41.—Extent of injuries of spleen, treated by resection of three-fifths of the viscus.

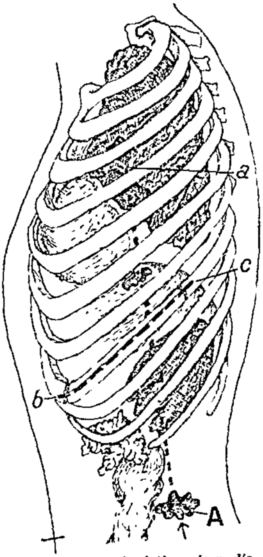
CASE 34.—Wounded 10.20 A.M., May 26th; on admission 5 P.M., lacerated wound below right twelfth rib, missile felt at front part of sixth rib under skin, which was punctured, and discoloured over wide area. Operation at once, gas-oxygen, intercostal and lumbar nerves blocked with novocaine. Excision of tissue round foreign body, with wide area of skin, fractured sixth rib, and wound of diaphragm; distinct fæcal smell on opening pleura, excised tissues stained with intestinal contents; pleura irrigated with eusol and wound sutured without drainage. Entrance wound excised and enlarged by oblique incision to linea semilunaris; right kidney, torn right across, removed; through-and-through wounds of hepatic flexure, causing considerable soiling, sutured, and peritoneum closed; wound otherwise left open except for two sutures to rectus sheath; Carrel tubes to abdominal wall and perinephric fat; 20 oz. blood transfusion; pulse at end of operation 120, blood pressure 70. June 1st to 10th, fæcal fistula; 11th, chest wound healed by first intention, abdominal wound granulated to skin, one inch wide at widest part; patient sent to base. Wrote from England a few weeks later "wound almost completely healed, awaiting a ship for repatriation to New Zealand."

FIG. 3.



CASE 34.—Shell wound of the right kidney, colon, diaphragm, and pleura. A to *a* = course of missile; *b* to *c* and *d* = positions of operation incisions.

FIG. 4.



CASE 41.—Wound of the spleen, diaphragm, omentum, and lung. A = entrance wound; *a* = missile retained in lung; *b* to *c* = site of operation incision.

When the direction of a missile nearly corresponds to the long axis of the body, it may have a long course in abdomen and thorax before being arrested; here the problem that presents itself is how to expose all the injured structures with the minimum of additional trauma to the patient. Resection of the eighth or ninth rib gives sufficient exposure of the thorax and abdomen for most injuries; if necessary the thoracic incision can be prolonged into the abdominal wall. The following case illustrates these points, and is also of interest because it was the first occasion on which I performed a partial resection of the spleen;

this appeared to me to be less severe for wounds not involving the hilum, but it would be hardly feasible by any other exposure. (Fig. 4.)

CASE 41.—Wound of spleen, diaphragm, and lung; resection of damaged part of spleen, large projectile removed from upper lobe of lung. Wounded by shell at 1 P.M. Six hours later, condition good, pulse 76; large laceration six inches to left of third lumbar spine. Severe dyspnœa, left abdomen rigid, no vomiting or hæmoptysis. X rays show missile in upper part of lung, and large hæmothorax. 8.30 P.M., pulse 84, operation: light sleep by chloroform on one layer of gauze, lower seven dorsal and upper three lumbar nerves blocked with novocaine. Anterior six inches of eighth rib and costal cartilage removed, pleura opened and cleared of blood; piece of shell embedded in upper lobe of lung, removed; lung track cleaned, irrigation with eusol; wound at highest point of diaphragm sutured and fixed to sixth interspace; pleura closed by diaphragm-intercostal suture. Incision near margin of diaphragm; spleen bleeding from severe lacerations of its lower third extending right through it in an area three inches wide (Fig. 5); resection of lower three-fifths of spleen, suture of capsule; wound closed with rubber drain to spleen. Wound of entry passing through abdominal wall to outer side of colon excised, peritoneum sutured, *rest of wound packed with 1 per cent. iodoform* paraffin gauze. Pulse at end of operation 92. Next day, pulse 92, no dyspnœa, vomited twice slightly; third day, very fit, pulse 88; fourth day, drain removed; seventh day, stitches removed, upper wound healed, loin wound appears aseptic; nineteenth day, sent to base, loin almost healed. Went to England a few days later, and returned to his home two months afterwards, without complications.

For anatomical reasons wounds which perforate the left side of the diaphragm offer more variety than those on the right, and are more often responsible for hæmorrhage from spleen, mesentery, or omentum, penetration of stomach or intestine, and escape of abdominal organs into the pleural cavity; wound of this side also causes more respiratory and cardiac embarrassment.

The common varieties of wounds of the spleen were gutter wounds of the outer surface, through-and-through perforations with radiating splits of the capsule, severe lacerations, and complete separation of a segment. Wounding of the spleen is not necessarily an indication for operation, but as a general rule it is safer to look and see than to "wait and see." *In my earlier cases I sutured the lacerations* or removed the organ; when I realised the ease with which the spleen could be exposed by an incision through the outer part of the diaphragm I was able to resect the damaged portion in some cases. In many cases wounds of the spleen are associated with injuries of other viscera; in the following one the missile was retained in the pancreas.

CASE 35.—Shell wound of diaphragm, spleen, and pancreas. Wounded by shell fragment fracturing ninth left rib: vomited at once. On admission, collapse, pulse 130, general abdominal rigidity: X rays show missile 1½ inches from midline, 6 inches deep from front. Operation seven hours after injury, wound and 5 inches of rib excised, prolapsed omentum reduced, wound of diaphragm excised, pleura closed, pulped spleen removed, track traced into pancreas, missile not removed; closed without drainage; 25 oz. blood transfusion. Recovery without incident.

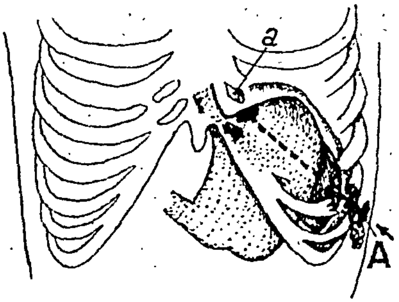
In several cases severe hæmorrhage occurred from omentum as a complication of a wound of the left side of the diaphragm, the viscera escaping injury. The stomach is often implicated in abdomino-thoracic wounds; it may be wounded, it may prolapse through the diaphragm, *and in one case a gastric fistula* discharged through a wound of the lung. In these wounds it is often the cardiac end of the stomach that is injured, and this region and the posterior surface are more accessible through a thoracic than an abdominal incision.

The following case illustrates the ease with which a lacerated wound one inch from the cardia was sutured, and the posterior surface explored by tearing through the gastro-splenic omentum. The missile had remained in the lumen of the stomach. (Fig. 6.)

7.—Abdomino-thoracic wound of spleen and stomach. by fragment of shell entering seventh left : no vomiting. Seven hours later, pulse 108, left rigidity, catch in respiration; X rays—missile related to left suprarenal body. Operation eight hours after injury, gas-oxygen, intercostal nerve-block; excision of wound and 6 inches of fractured eighth rib and cartilage, prolapsed omentum reduced, diaphragm wound excised, pleura cleansed and closed. Incision prolonged to abdominal wall, lacerated wound of greater curvature of stomach one inch from cardia sutured, through-and-through wound of spleen not bleeding; closed without drainage after careful examination of whole of posterior surface of stomach. No shock or vomiting; healed by tenth day, except for one stitch abscess of abdominal wall. Wrote from England two months later "fully recovered, no complications."

Injury of the kidneys was a common complication, its seriousness depending on hæmorrhage, and later perinephric infection; the former was usually controlled by packing, occasionally by suture; in many cases lumbar or transpleural nephrectomy was necessary. For all wounds of the kidney it is necessary to drain the perinephric tissue early; when a wound of the diaphragm is also present it is important to close it, for in many cases an opening in the muscle allowed infection to gain the pleura. The effects due to the actual opening in the diaphragm have already been indicated; that most worthy of special notice is the prolapse of abdominal contents into one or other pleural sac. On the right side this complication is unusual, but portions of liver may be found lying free in this side of the thoracic cavity, and occasionally omentum prolapses. On the left side the omentum very frequently passes through the wound of the diaphragm, and this fact forms a definite indication that all wounds of the left side of the muscle should be repaired by operation. The occurrence of gastric or intestinal fistula opening through the thorax is uncommon; a case wounded in 1917 developed a gastric fistula, opening through the left lung and chest wall.

FIG. 6.



CASE 37.—Shell wound of the diaphragm, spleen, and stomach, with prolapsed omentum. A = entrance wound; a = wound near cardia of stomach.

CASE 51.—Admitted with leaking wound of posterior part of left intercostal space, vomiting, and severe collapse; the general condition improved, but on the fifth day escape of gastric juice was apparent, and on the seventh day I made a jejunostomy under local anæsthesia. The man died on the following day, and autopsy showed the whole of the stomach in the left pleural sac, a wound of its posterior wall communicating with the exterior by a track passing through left lung, which was adherent to the stomach and parietal pleura; no sign of general infection of pleural cavity or peritoneum.

LATE EFFECTS OF INJURIES OF THE DIAPHRAGM.

Most of the late effects which follow rupture or wounding of the diaphragm fall into three groups: (1) the results of a foreign body embedded in the muscle; (2) scarring and adhesions; (3) diaphragmatic hernia.

Foreign Bodies Embedded in the Muscle.

The most prominent symptom of a projectile embedded in the muscle is fixed pain, produced especially by the effort of lifting, by coughing, and by deep inspiration; some patients complain of attacks of suffocation, others of irritating cough. The patient learns to keep the affected side of the muscle immobile.

The diagnosis depends on localisation by X rays. As to treatment, the foreign body should be removed if symptoms are sufficiently severe, and this is best done by open transpleural operation, which allows the release of pleural adhesions, often responsible for many of the patients' symptoms.

Scarring and Adhesions.

Adhesion of a scar of the diaphragm to the chest wall and to the viscera in relation to it appears to cause definite disability. These patients complain especially of pain on exertion, situated in the region of the wound, in the lower thorax and upper abdomen, and just below the clavicle; in some there is præcordial pain and palpitation. Many soldiers wounded in the chest have complained subsequently of gastric symptoms, especially loss of appetite and vomiting; these symptoms may be due to immobility of the diaphragm, adhesions, and sometimes to a communication between the pleural and peritoneal cavities. Undoubtedly diaphragmatic hernia is a more common sequela of wounds of the left side than has been realised, and many cases have been overlooked; there is a danger of diagnosing adhesions alone in patients whose symptoms are really due to hernia, and this condition should always be suspected in men complaining of pain and attacks of vomiting. The presence of adhesions involving the diaphragm can be demonstrated by X rays.

I saw recently a pensioner who was wounded in the left thigh by a rifle bullet in August, 1915. There were two scars below the left iliac crest, the lower one being circular, the other, immediately above it, was vertical and about two inches long; the wound had always been considered to be a superficial one of the through-and-through type. There was no sign of bone or muscle injury, but the man was complaining of pain in the chest, cough, and expectoration, palpitation on exertion, and shooting pain under the heart; he was thin, pale, and cachectic, with a pulse-rate when resting of 120. Rhonchi were heard in the lower part of the left lung. I suggested X ray examination, and this showed a bullet in the left chest, just above and outside the apex of the heart. The military history of this man is interesting, for he was sent back to duty overseas six weeks after being wounded, and he remained with the army abroad until April, 1919. He succeeded in gaining admission to hospital for two months in 1917 and for two and a half months in 1918, the diagnosis being made of bronchitis on the first occasion, and of pyrexia N.Y.D. on the second occasion; I saw him because he was appealing against an inadequate pension.

I have mentioned this case because the significance of wounds of this type is apt to be overlooked. As to the treatment of pleural adhesions involving the diaphragm, their separation during operations undertaken primarily for the removal of foreign bodies has seemed to play an important part in the relief given to the patients, but it is a question if thoracotomy is a justifiable operation for adhesions alone; not that the operation itself is dangerous, but it is difficult to ensure a perfectly dry pleura at the end.

Diaphragmatic Hernia Resulting from Injury.

By far the most important of the late results of wounds and other injuries of the diaphragm is the persistence of a communication between the pleural and peritoneal cavities; it was known more than a century ago that wounds of this muscle rarely healed, and it seems likely that as a result of the recent wars there are now living a larger number of men suffering with diaphragmatic hernia than at any previous time.

There has been considerable discussion on the question of how long after the injury the hernia usually occurs, and in most cases the onset of symptoms has been so insidious that it is impossible to put a date to their commencement; sometimes the first definite symptoms have followed a sudden strain or prolonged effort, as in the case recorded by Barton[2] where about five months after being wounded the man, who had been sent back to France, vomited every day after his first long march, and continued to do so for nine months.

Traumatic diaphragmatic hernia is infinitely more common on the left side, though hernia of omentum into the right pleural sac sometimes occurs; hernia through the central tendon into the pericardium is very rare. The commonest position for the hernial orifice is in front of and lateral to the œsophageal opening.

Pathology.—In the great majority of instances there is no true hernial sac, but a peritoneal sac is sometimes present and limits the size of the hernia. The edges of the hole in the diaphragm may be sharp-cut and fibrotic, or they may be unrecognisable, the muscle gradually thinning and being incorporated with the surface of the viscera prolapsed; these are most commonly the stomach, the transverse colon and hepatic flexure, the small intestine and the spleen, in order of frequency, but occasionally duodenum, pancreas, and liver have been involved. The viscera become adherent to the margin of the opening and to thoracic contents: adhesion to pericardium and parietal pleura is usual, adhesion to the lung is less common; these adhesions are often very firm and constitute the most serious difficulty in treatment. The stomach becomes dilated and hypertrophied, and in some cases the sharp edge of the diaphragm has produced an ulcer of the part of the stomach on which it pressed; the heart is displaced, the lung is compressed and collapsed. Gastric and intestinal fistula have occurred occasionally. Strangulation is a frequent complication, and in many instances the condition has not been suspected until its discovery at an operation for acute obstruction.

Symptomatology.

The cases can be divided into two main classes: (1) those presenting symptoms of chronic diaphragmatic hernia subject to exacerbations; (2) cases of acute obstruction and strangulation.

1. *Chronic type.*—It is likely that there exist a number of unrecognised cases in which a very small part of the stomach is herniated as the result of an old wound; it is evident that if we can diagnose these while the prolapse is small, the dangers of cure are much diminished. The symptoms of these small herniæ are not very definite, but the occurrence of heartburn, loss of appetite, and pain after meals, palpitation, occasional vomiting, dysphagia, dyspnœa, pain on exertion, gradual loss of weight, and constipation, in a man whose scars indicate a possible old wound of the left side of the diaphragm, should be viewed with grave suspicion. In most of the recorded cases there has been a large portion of the stomach, with or without other viscera, prolapsed into the left pleural cavity. The involvement of the stomach in nearly all cases is responsible for the most prominent symptoms; these may be almost entirely subjective, and one is struck by the number of cases recorded where the sufferers have been looked on as malingerers.

Pain is a prominent symptom; it may be situated in the epigastrium, the lower abdomen, the affected side of the chest, especially below the clavicle, or in the shoulder. Præcordial pain is sometimes present. The pain comes especially very soon after any food or drink is taken, and may be very severe; it is relieved by vomiting, and increased by exertion, especially weight-lifting. Occasionally it has been noted that the pain goes at night, when the patient lies down; sometimes it is only relieved by lying on one particular side; in the case described by Sir Charters Symonds,[3] when during exacerbations the patient sat up with his back flexed, straightening of the back caused acute pain. There may be a sense of great distension after food, referred to chest or abdomen, sometimes a feeling of suffocation.

Vomiting is an important symptom, increased by exercise; often fluids only can be retained. The vomit may contain bile or altered blood. A most valuable clinical observation in regard to the vomiting was described by Gaudier and Labbé.[4] The patient, extremely emaciated, could only retain fluids, and it was noticed that he did so much more easily when lying; by keeping him recumbent before and after meals, his general condition improved and he was able to undergo successfully a severe operation. This clinical fact has since been confirmed by many observers, and it constitutes perhaps the most typical single sign of diaphragmatic hernia.

[3] THE LANCET, 1917, i., 18.

[4] Bull. et Mém. Soc. de Chir. de Paris, 1918, xliv., 383.

In some cases there has been dysphagia, but this is commoner in the congenital herniæ. Constipation is almost invariable, and often precedes other symptoms. The patients become emaciated, anæmic, and cachectic, and they are usually nervous; the wasting may be very gradual, for the patients learn to confine themselves to milk taken frequently. The respiratory symptoms are pain on deep breathing and dyspnœa; sometimes there are attacks of suffocation, particularly at night. The cardiac symptoms are palpitation and præcordial pain.

Objective evidence is often slight, but some of the following signs may be present: abnormal flattening of the abdomen, and on palpation a sense of emptiness of epigastrium; the abdomen is usually relaxed, but there may be local rigidity and tenderness. The movements of the left side of the thorax are diminished, and fullness may be obvious; the stomach resonance may extend above the nipple. Not uncommonly the breath sounds of the left chest are faint, and accompanied by gurglings and borborygmi, which may be perceptible to the patient at each respiration, especially towards evening; splashing sounds may be elicited.

The close relation of stomach to pericardium gives a persistent tachycardia, increased by exertion and meals; the heart is slightly displaced, and tinkling sounds are sometimes produced by its impulse striking the stomach; these may be heard by the patient.

2. *Acute type.*—Acute obstruction and strangulation produce a condition of great danger, and the recorded instances of recovery are not numerous, on account of the emaciation of the patients and the difficulties of diagnosis. The typical picture is one of acute obstruction with an empty, even hollow, abdomen.

Diagnosis.

In the chronic stage the cases have been most often mistaken for pyloric obstruction or pneumothorax. However, in recent years the technique of their examination by X rays has been carefully studied. The comparison of the position of a single scar with the localisation of a retained missile may give a clear indication of diaphragm injury; simple radiography may show an opaque area to the left of the heart shadow, irregularity of the diaphragm, and displacement of the heart. But it is from radioscopy with the swallowing of bismuth or barium emulsion that the clearest evidence is obtained; repeated examination and considerable manœuvring may be necessary to get the emulsion into the supra-diaphragmatic pouch, and the patient must be examined facing the observer and obliquely, upright and supine.

Treatment.

Little can be done, apart from operative procedures; these fall into three groups: (1) the abdominal method; (2) the thoracic method; (3) the combined abdomino-thoracic method.

1. The most commonly employed abdominal incisions are one placed close to the costal margin, which is divided sometimes, and a high left paramedian incision joining a transverse one at the level of the umbilicus.

2. In the thoracic method of approach, a portion of the sixth, seventh, or eighth rib is resected or mobilised; by removing or turning up all the rib in front of its angle a good view is obtained.

3. The first description of the employment for these cases of an incision opening abdomen and thorax together was apparently given by Bérard.[5] The incision is made over the seventh, eighth, or ninth rib and continued forwards and downwards in the abdominal wall; the rib is resected and the costal cartilage divided. I have used this incision on many occasions for dealing with the results of abdomino-thoracic wounds, and it seems the most suitable for difficult cases of diaphragmatic hernia. Probably it is best to commence by resecting or turning up the rib, the incision being prolonged to the abdominal wall later, if it proves necessary.

There has been a good deal of discussion of the relative merit of the abdominal and thoracic methods. The main objection to the thoracic route seems to be that surgeons are more practised in abdominal than thoracic surgery, and that secondary conditions, such as gastric ulcer, may necessitate intraperitoneal procedures. The abdominal incision will certainly be used for most cases dealt with in the acute stage, for these come to the surgeon as abdominal emergencies; in most of them empty intestines make access to the diaphragm from below fairly easy. But in a chronic case the thoracic method, or the abdomino-thoracic one, possesses considerable advantages, giving a clear view and allowing more adequate repair of the diaphragm.

Stages of Operation for Diaphragmatic Hernia.

After opening abdomen or thorax the prolapsed viscera and omentum must be freed by dividing the adhesions; these may be very dense, and care must be taken not to drag on the pericardium, and that if important structures must be cut they shall be those most easily repaired; naturally it is better to risk opening the stomach than the pericardium or colon. The defect in the diaphragm may be very difficult to define, and in some cases adhesions have been so dense that it has been considered unwise to attempt their separation. In a case recorded by Baumgartner and Herscher[6] the stomach was firmly adherent, and the spleen's outer surface was fixed to a scar of the thoracic wall; the surgeon freed the small intestine, omentum, splenic flexure, and the stomach from the pericardium and front part of the diaphragm, leaving the adhesions of the back of the stomach and the spleen intact; he then adopted an expedient used previously by Lecéne, closing the defect by suturing its edges to the stomach and to scar tissue at the lower part of the spleen; the result was completely satisfactory.

A dangerous step is the reduction of the stomach, for its contents may be forced into the œsophagus and flood the only sound lung; it is recommended that the thoracic pouch of stomach be emptied by aspiration before reduction, a safeguard only possible by the thoracic exposure. Careful closure of the gap in the diaphragm is important and is more easily achieved from above. The last stage of the operation is to close abdomen and thorax after specially careful attention to hæmostasis; when, on rare occasions, it is advisable to drain the pleura a valvular method should be employed.

Conclusion.

We may conclude, then, that in operations for strangulation and acute obstruction the abdominal route will be employed as a rule. In chronic cases the thoracic method of approach has certain advantages; it allows adhesions to be divided under better observation, with more safety and better control of bleeding; the stomach pouch can be emptied before reduction; accurate suture of the diaphragm and any plastic measures demanded can be carried out more satisfactorily; and the pleura can be cleansed and its dryness ensured at the end of the operation. If special difficulties arise, or a gastro-jejunostomy is indicated, the thoracic operation is converted into an abdomino-thoracic one by prolonging the incision. In all types of operation the pleural cavity is open, so that the slight risks of operative pneumothorax are equally present.

THE FÆCES IN ALIMENTARY DISORDERS.*

BY ROBERT COOPE, M.D., B.Sc.,
LECTURER IN BIOCHEMISTRY, UNIVERSITY OF LIVERPOOL
HON. ASSISTANT CHEMICAL PATHOLOGIST, LIVERPOOL ROYAL INFIRMARY.

IT is important to have in mind the fact that normally, on a digestible diet, the only food residues found in the stools are remnants of muscle fibre and the tough debris of vegetables. The fæces are made up of voluminous soap gels, residues of intestinal secretions, excretions, and innumerable bacteria, many of them dead, and only when indigestible cellulose is given are they augmented by vegetable residues, imprisoning in their cellulose and woody envelopes a certain small amount of starch. Even here art has been brought to the help of nature; and by means of cooking, many vegetable foods have been made almost wholly digestible, except for their tough cellulose skeletons. Hence, if foodstuffs occur in the fæces in any notable amount, there is something abnormal, and this abnormality may be due to one of three things, viz.: (*a*) failure of digestion somewhere; (*b*) failure of absorption; or (*c*) hurrying on of the food, so that there is not time for proper digestion or absorption—i.e., diarrhœa.

The diet, however, paradoxically enough, does influence the character of the stools, for the intestinal secretions and the bacterial flora depend a good deal upon the diet which calls them forth. If one might venture upon a description of the normal stool of an ordinary mixed diet, one might say that it is a moulded, fairly firm, more or less cylindrical body, reaction neutral or slightly alkaline to litmus, coloured brown chiefly by the pigments derived from the bile, containing little or no food residues.

However, it is easier to lay hold of the conception of an abnormal stool. Here the fæces have no health in them because either they contain things they ought not to contain—notable quantites of food residues, abnormal substances derived from the gut walls, such as blood, serum, pus, mucus, or from the lumen, such as intestinal calculi, "sand," or parasites—or they may not contain the things they ought to contain, particularly the derivatives of bile pigment. It is a very general opinion that examination of the fæces involves intricate and very specialised chemical operations, but I am convinced that though these are sometimes necessary, in the great majority of cases a comparatively simple technique is adequate for clinical purposes.

Control of Diet.

There are, however, one or two preliminary considerations which must be mentioned. In the first place, the controlling of the diet is a most essential and important matter if valid deductions are to be drawn. I find it useful to examine upon three types of diet:—

(1) It is often most valuable to see the fæces corresponding to a patient's usual diet, and to examine more than a single stool; a rough idea can then be obtained of how he responds to the diet he is in the habit of taking.

(2) Then for two days a milk diet is given, and its typical canary yellow stools make it possible to do a properly controlled test for occult blood and soluble albumin.

(3) A test diet is then given, either in the form of a single meal or a series of meals. A convenient single test-meal is the following: Bread (may be toasted), 3 oz.; lean beef, underdone (minced if preferred), 2 oz.; milk, 1½ pints; potatoes, mashed with some of the above milk, 10 oz. This can be given as a midday meal, followed by a milk diet for the rest of the day. Before, during, and after the meal a cachet of charcoal is given, in order to mark it off from the preceding and subsequent milk diets. By noting the time of the test-meal and the first subsequent stool which is coloured grey with charcoal granules one can gain a rough idea of the length of time the meal has taken to pass through the alimentary tract.

For some days previously drugs should be withheld, especially oily bodies like olive oil or liquid paraffin, which may appear as excess of fat in the stools; purgatives, too, should not be given, for they may cause a marked irritation of the gut, and the production of considerable quantities of mucus, or they may interfere with the normal digestion of the food. The stools should, of course, be examined as fresh as possible.

At the very outset not a few important deductions may be made from the form, consistency, colour, odour, and general characteristics of the stool, but we must do no more than mention their possibility. Nor can we stay to discuss the sieving or "tamissage" of the stools, valuable though it is where intestinal concretions, "intestinal sand," parasites, &c., are suspected. Let us pass on to a discussion of the macroscopical, microscopical, and chemical examinations of the fæces—the three divisions of a "simple technique."

Macroscopical Examination.

The stool is mixed into a homogeneous mass, either as a whole or in parts (if there is any obvious difference in the naked-eye characters of various parts of the stool). A piece of fæces about the size of a walnut is placed into a conical glass, and with the aid of a glass rod and some warmish water made into an emulsion. Portions of this are poured into a Petri dish, diluted with water, if necessary, and examined against a background partly white and partly black.

Various things may be seen—vegetable debris, tiny brown rods of muscle fibre, actual masses of undigested meat (which occur sometimes in the stools of hungry gourmets who bolt their food), white dots of the so-called "potato granules," parasites, possibly epithelial debris; more notably, typical white fragments of connective tissue, and flakes of mucus, intimately mixed with the fæces, transparent or cloudy, stained greenish yellow or brown with the bile pigment derivatives. Some of these may be difficult to distinguish the one from the other—vegetable debris, parasites, connective tissue, and mucus are not infrequently confused; but experience soon enables one to avoid mistakes, and if there is any doubt, the suspected fragment should be transferred to a watch glass containing a little water and examined microscopically at leisure. A simple microscopic examination is usually quite sufficient to distinguish them. Certain appropriate chemical and staining methods can be used if necessary.[1] The most important abnormal things to notice in this part of the examination are connective tissue, flakes of mucus, and parasites.

Microscopical Examination.

A small amount of the mixed fæces is taken up with a glass rod, put on to a slide and pressed out well with a cover-glass. One or two such preparations may be made from different parts of the stool, and usually it is useful to make an iodine stained preparation, leaving it to stand for about 15 minutes before covering with the cover-glass. Standing out against an amorphous background, one may see, normally: (*a*) elastic tissue fibres (rare and of no pathological significance); (*b*) muscle fibre remnants, small hyaline fragments, stained yellow or brown with bile derivatives, occurring infrequently, not more than one or two to the low power field at most: possibly these are pigmented shells of sarcolemma; (*c*) yellow amorphous masses of soaps and fatty acids occurring infrequently in the preparation; (*d*) vegetable debris, which takes many shapes and is apt sometimes to be confused with parasites and their ova.

Abnormally there may be seen certain food residues: (1) Striated muscle fibre, or muscle fibre only partially attacked by the digestive juices—present in excessive amount, several to the field, and consistently seen throughout the whole preparation. (2) Fat. There may be present globules of neutral fat, flakes of neutral fat or fatty acid, crystals of fatty acids, soap rings or needle crystals. These can be differentiated by certain chemical and staining properties, details of which may be found in the text-books. (3) Starch granules, stained blue with iodine, occurring as single granules: or as "potato granules," with the appearance of capsules enclosing several small granules. Sometimes they stain red owing to the digestion of starch into erythrodextrin.

---

* A paper read before the Pathological Section of the Liverpool Medical Institution, March 17th, 1921.

[1] For further details of these examinations, a book such as Cammidge's "The Fæces of Children and Adults" should be consulted.

Mucus flakes should always be microscoped, staining is not necessary. Leucocytes, red blood corpuscles, catarrhal cells from the intestine, triple phosphate crystals, epithelial debris, &c., may be seen entangled in them. It is extremely difficult to recognise epithelial debris or leucocytes in the original preparation if the stool is at all formed. In certain fluid stools, notably the diarrhœic stools of typhoid infections, there may be actually little else save leucocytes in suspension in a very foul and putrid liquid.

Parasites or their ova may be seen, and certain crystals may be present, especially those of triple phosphate, which may be deposited in stale fæces, or may occur in large numbers in the putrid, alkaline stools of certain colites. Some workers suggest that a Gram-stained bacteriological film should be made. Personally, I have found little help from it, and in our present state of knowledge it seems to me not worth while, for clinical purposes, to take time over it. It is another matter if definite bacteria are suspected, such as the typhoid group or tubercle.

Chemical Examination.

The reaction to litmus is taken. One then examines for one normal and two abnormal constituents. The normal constituent is stercobilin or hydrobilirubin, derived from the pigment, bilirubin, of the bile by the reducing action of the intestinal bacteria.

A most convenient test for it is to rub up a little fæces with a saturated solution of mercury perchloride and leave to stand, when after a few hours a more or less intense pinkish-red colour develops. The reaction goes much more quickly at 37°C. If some of the well-mixed fæces and the $HgCl_2$ solution are put into a test-tube, one has also a very convenient method of testing for one of the abnormal constituents—coagluable protein, or so-called soluble albumin.

The difficulty in testing for soluble albumin is to obtain a clear fæcal filtrate. Prof. Ramsden and I hope to publish shortly a test which is time-saving and reliable; but for the present I will only mention the mercury perchloride method described above for stercobilin. The rationale of it is the same as that for the method of clearing coffee with a little egg albumin. A normal stool when mixed with water or a solution of mercury perchloride remains a turbid suspension; if soluble albumin is present, however, the metallic salt precipitates the protein, and the precipitated protein carries down with it the other particles in suspension in the fluid, so that the supernatant liquid, if left to stand, instead of remaining turbid becomes clear within a few hours.

Blood, the other abnormal constituent, must be looked for on a controlled diet, and I generally use Weber's guaiacum test.[2]

One other point that may be mentioned—if trouble is suspected in the large intestine, it is often useful to wash out with normal saline some short time after the passing of a stool, and examine the contents of the wash-out chemically both for blood and for soluble albumin, and (after centrifugalising) microscope the deposit.

Discussion.

The abnormal findings can be divided into two categories: (*a*) absence of normal constituents; (*b*) presence of abnormal constituents.

In the first category comes *stercobilin*. If stercobilin is absent, one may safely draw the deduction that bile is not reaching the intestine. The cause may lie in the liver cell itself, or in obstruction of or in the bile passages. There is, unfortunately, no accurate quantitative method for estimation of stercobilin; however, when it is present, by using a uniform technique, a rough idea may be obtained as to whether there is much less than normal.

In the second category are certain food residues—blood, soluble albumin, and mucus.

Food Residues.

(1) *Connective Tissue.*—If connective tissue reaches the fæces in any marked amount, one can conclude with complete confidence that there is a failure of gastric digestion. The scleroproteins of tendons and connective tissue generally, are left undigested, unless the gastric juice has prepared them for further digestion.

(2) *Undigested Muscle Fibre* (creatorrhœa).—Normally, only occasional remnants or shells of meat fibre are present in the stools. Abnormally, I would mention two important types of case:—

(*a*) In the first type there is considerable excess of muscle fibre, though most of it is more or less attacked by the digestive juices. One may term it "partially digested muscle fibre." A clinical example may illustrate this.

A patient complained of overwork during the war; recently, loss of weight, pain about two or three hours after food, flatulence, nausea, occasional attacks of diarrhœa, severe headaches; marked tenderness to pressure over epigastrium. Blood pressure 220 mm. Urine shows a marked excess of indoxyl. No evidence of gastric or duodenal ulcer. The stools of his usual diet show a markedly alkaline reaction to litmus, enormous quantities of partially digested muscle fibre, definite smell of protein putrefaction, and mucus flakes in excess. On the usual test diet the same picture held, and suggested that for some obscure reason (possibly functional trouble of the pancreas) there was an inability to deal adequately with meat fibre, and secondarily, irritation of the gut by bacterial putrefaction products of this undigested muscle fibre, with resulting colitis, mucus flakes, and probably also some intestinal toxæmia. This view was supported by finding that on a carbohydrate diet with restriction of meat the blood pressure fell within a week to 120 mm. of mercury, the mucus in the stools disappeared, and the general condition improved. He is now practically cured, though it still remains necessary—over twelve months after I first saw him—for him to forgo any carnivorous indiscretions, such as game.

(*b*) The second type shows an excess of meat fibre in the stools, and practically all of it has retained its striations—i.e., true creatorrhœa. This condition is almost invariably met with when there is inadequacy of the pancreatic juice, for the pancreatic secretion is essential for the digestion of the striations. Hence, provided that diarrhœa can be excluded, the appearance of striated muscle fibres in the fæces indicates that there is a pancreatic insufficiency, possibly due to obstruction (as in carcinoma of the head of the pancreas), or maybe to lack of production (as in extensive cirrhosis of the gland).

(3) *Starch Grains.*—These may indicate an ordinary diarrhœa or the condition of so-called carbohydrate intestinal dyspepsia, which occurs especially in children. Here the gut cannot deal properly with the carbohydrates supplied to it, either because they are excessive in amount, or because there is some infection or catarrh of the small intestine. Their presence has no necessary relation to pancreatic disease.

(4) *Fat.*—An important and much discussed matter and one into which many unnecessary complexities have been imported. There are two fundamental questions to investigate here: (*a*) Is there excess of fat (of any or all types) in the stool; (*b*) If so, is it an excess of split or unsplit fat?

(*a*) If a uniform technique is used, as a general rule conclusions quite adequate for all clinical purposes can be drawn from a microscopic examination. Adult stools contain normally 15 to 25 per cent. of their dry weight of "fat," including under this head all substances soluble in ether. On a test diet, if the fat present is above 40 per cent., it is almost invariably recognisable microscopically. Often the limit is even less than 40 per cent. Personally, I do not think that important deductions can be drawn, even if accurate quantitative fat estimations are made, from small variations in fat content. Nor do I think that an accurate determination of the relative proportions of split or unsplit fat gives information at all commensurate with the labour involved.

(*b*) Is it an excess of split or unsplit fat, microscopically? Unsplit fat, of course, means neutral fat—the glyceride of a fatty acid; split fat means fatty acids or their salts—the soaps. Whether the split fat consists of the free fatty acid or the soap depends practically entirely upon the acid or alkaline reaction of the intestinal contents, and therefore, as the important point is to learn whether the neutral fat of the food has been split into glycerine and fatty acid to the usual extent, no clinical purpose is served by distinguishing between the two types of split fat—free fatty acid and soaps. Hence for clinical purposes it is desirable to classify the fæcal fat in the two broad categories of "split" and "unsplit" fat.

---

[2] For further details see paper "On Soluble Albumin and Blood in the Stools," THE LANCET, 1920, ii., 291.

The fats are split chiefly by the lipase of the pancreatic juice, aided greatly by the presence of bile; their absorption from the gut depends overwhelmingly on the presence of the bile acids of the bile. However, the intestinal juice appears sometimes to be able to take on the power of splitting fat, and certainly fat may also be split by the action of bacteria in the large intestine.

Thus, one may conclude that (*a*) the presence of excess of neutral fat in the stools probably indicates pancreatic insufficiency, but sometimes shows merely a very rapid passage of food through the gut, as in gastrocolic fistula (on the other hand, even with pancreatic insufficiency, the fat may be split in the small bowel and absorbed, or split in the large bowel and escape absorption); and (*b*) excess of fat, which is split fat, may indicate (1) marked diarrhœa; (2) pancreatic insufficiency (where means other than the pancreatic juice has split the fat); (3) lack of absorption due to absence of bile, or to disease of the gut wall (for example, amyloid disease, sprue).

It is obvious, therefore, that these various factors must be carefully weighed in interpreting an examination of the fat content of a stool, whether with positive or negative indications.

5. *Blood and Soluble Albumin.*—Of these, little must be said, important though they are. There is no need to emphasise the significance of occult blood in the stools of a controlled diet. Soluble albumin, or coagulable protein may come, rarely, from the food "albumins"—in severe diarrhœa, for example, especially in children; more usually it comes from the blood serum of a hæmorrhage, or from serous exudate into the gut. It is so rapidly digested that if present in the stools it indicates exudate or bleeding not too far from the anus, or else a very copious exudate or bleeding higher up the gut. It may occur, notably, in ulceration or carcinoma of the colon.

6. *Mucus.*—Normally the comparatively small amount of mucus secreted by the small intestine is digested before it reaches the ileocæcal valve, and in the large intestine the mucus there secreted is so intimately mixed with the fæces as to be unrecognisable either macroscopically or microscopically. When, however, there is excess of mucus produced, either by infection or irritation, it appears in the stools roughly in one of two forms: (*a*) covering the surface of the stools—maybe forming an actual membrane; or (*b*) small flakes intimately mixed with the fæces.

Broadly speaking, the large bowel is divided into two portions with separate functions. In the cæcum, ascending colon, and part of the transverse colon—the proximal part of the large intestine—churning of the fluid fæces occurs, with the absorption of water. More or less solid parts of fæces are then passed into the distal part of the bowel, whose function is mainly occupied with defæcation. A consideration of this division of function helps in the interpretation of the different appearances of mucus. Excess of mucus produced in the small intestine, or the initial part of the large bowel, will be intimately mixed with the fæces in the form of flakes; mucus produced in excess in the terminal half of the large intestine will tend to surround the formed fæces. It is thus obvious that mucus *flakes* are not directly due to a mere banal constipation. The fæces in the cæcum and ascending colon are fluid, and the mucus incorporated there is the response to irritation of the gut wall, perhaps from bacterial infection, perhaps from damaging chemical products (for example, those of protein putrefaction). On the other hand, mucus surrounding the formed stool is likely to be due directly to constipation. In putrid fluid fæces, as in typhoid, the abnormal mucus may be digested, and not appear in the stools at all.

Summaries of Illustrative Cases.

1. M. C. J., age 45, gastric pain for eight months, jaundice three months. Occasional vomiting, two months. Loewi's adrenalin reaction positive. *Urine:* Diastase index low; no sugar; bile pigments and salts present. *Stools:* No undigested muscle fibre, crystals of split fat in marked excess. No stercobilin. Laboratory report: "Complete obstruction to bile outflow. No evidence of pancreatic involvement." Diagnosis: Gall-stones. At operation a large stone removed from the common bile-duct.

2. M. J., age 51, jaundice four months, loss of weight, no vomiting. X ray showed (1) slight delay in emptying of stomach—no obvious cause; (2) no evidence of gall-stones. Provisional clinical diagnosis, malignant pancreas. *Stools:* Never any undigested muscle fibre, always crystals of split fat in excess, stercobilin present but markedly less than normal. *Urine:* No sugar, diastase normal. Report: "Some obstruction to bile outflow, but not complete. No evidence of pancreatic involvement." Operation: Stone in cystic duct just above the junction with the common bile-duct, impacted, but not completely blocking the bile-duct.

3. M. Q., six months previously insidious development of pallor and emaciation. One month later jaundice appeared, varying in intensity from time to time; liver enlarged but not nodular. No pain, appetite good. *Urine:* 0·83 per cent. sugar, diastase 30 units (normal 10 to 33). *Stools:* Large numbers of striated muscle fibres, split fat in moderate excess, stercobilin present though less than normal. Occult blood present, no soluble albumin. Report: "Pancreatic insufficiency, with some obstruction to bile outflow; occult blood is in favour of malignant disease." Operation (three months later): extensive growth found, involving the head of the pancreas and neighbouring structures. Death two weeks later.

4. Mrs. G., tumour in epigastrium, pulsating on occasion. No jaundice; pain, loss of weight. Clinician's diagnosis: Pulsatile tumour of the liver or pancreatic cyst. *Urine:* Diastase normal, trace of sugar said to have been present in one examination by a clinical clerk, but absent in all specimens sent to the laboratory. *Stools:* Nothing abnormal. Report: "No evidence of pancreatic disease." Operation: Pancreatic cyst as big as a large orange. (Thus in this case the fæcal examination gave no help.)

5. E. M., vomiting, loss of appetite, no blood in vomit. "Could only take fluids." Hard supraclavicular gland on left side. X ray showed a normal stomach. *Urine:* Indoxyl and urobilin in excess, diastase normal. *Stools:* Very alkaline, mucus flakes in great excess, containing many leucocytes and degenerated epithelial cells. No undigested muscle fibre. No blood. Soluble albumin in small amount. Report: "Inflammatory condition of large intestine with some exudate." Clinically it was decided that there was a carcinoma of the colon. Death from pneumonia. Post-mortem refused.

6. E. W., boy aged 12, with diarrhœa. Temperature 100°F. *Stool:* Very alkaline, quite fluid, no mucus; practically speaking, the stool was a suspension of leucocytes in a foul-smelling fluid. Soluble albumin in marked amount, no blood. Report: "Inflammation of gut, with exudate." Further examination showed organisms of *Paratyphoid B*, and the boy's blood gave the agglutination test.

Conclusion.

I have largely dealt with the stools of adults. Children's stools are almost a subject in themselves, and they present many problems not yet fully worked out. Nevertheless, though interpretation is often difficult, particularly in the stools of infancy, in many cases valuable assistance may be looked for from an examination of the fæces, notably in the obscure indigestions of childhood, intestinal catarrhs, and actual organic disease of the alimentary tract.

In conclusion, I would insist that examination of the fæces must be integrated with the clinical findings, usually with a thorough examination of the urine, sometimes also of the blood. All that I would claim for it is that not infrequently it provides data which the clinician finds very valuable in making his diagnosis.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.—The first register of members of the Chartered Society will be published early in the autumn. Members and certificate holders of the Incorporated Society of Trained Masseuses and the Institute of Massage and Remedial Gymnastics are reminded that unless they register before July 15th at the offices of the Chartered Society, at 157, Great Portland-street, London, W. 1, their names will not appear in the first register.

AN UNUSUAL TYPE OF ARRHYTHMIA IN MITRAL AND AORTIC DISEASE

WITH EXTENSIVE MYOCARDIAL DEGENERATION.

BY MAURICE DAVIDSON, M.A., M.D. OXON.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, BROMPTON HOSPITAL; LATE
MEDICAL REGISTRAR, ST. GEORGE'S HOSPITAL;

AND

H. G. BUTTERFIELD, M.A., M.D. OXON.,
LATE GRAHAM SCHOLAR IN PATHOLOGY, UNIVERSITY OF
LONDON, AND LECTURER IN CLINICAL PATHOLOGY,
UNIVERSITY COLLEGE HOSPITAL.

THE following case, which appeared to us to exhibit some features of interest, showed an extensive degree of myocardial disease in a heart so distorted owing to pathological changes that identification of the auriculo-ventricular node and bundle in serial sections was a matter of great difficulty. The fibrosis, which was visible throughout the entire musculature, appeared to have left the fibres of the bundle intact. The clinical features of the case were a little unusual.

History of the Case: Condition on Admission.

The patient, a man of 38, was under the care of Dr. James Collier; he was first admitted to St. George's Hospital on August 31st, 1918, complaining of cough, sleeplessness, and swelling of the legs, having been ill in bed about a fortnight. He gave a history of having had malaria in South Africa in 1899, and a history of rheumatic fever about the same date. He had suffered from shortness of breath and intermittent attacks of swelling of the legs for about three years previous to admission.

On admission on August 31st, 1918, the patient was thin, pale, and obviously ill, with a pulse of 44. The heart was enlarged, the rhythm being irregular; the liver was enlarged, tender, and pulsating; there were moist sounds at the bases of both lungs; the legs, scrotum, and penis were œdematous. Tincture of digitalis was given in the usual doses. On Sept. 3rd the œdema of the genitals had disappeared; on the 9th the patient was not so well, and there was general anasarca; the pulse was slow and irregular from premature beats.

After some days the œdema disappeared, and the patient was discharged on the 29th. There was a well-marked systolic bruit at apex and base, and an aortic diastolic bruit conducted downwards and to the left across the sternum. During the above period the radial pulse varied in rate between 26 and 70 per minute. For the first few days it was between 26 and 40, but on Sept. 3rd it rose to 62, and afterwards continued to average about 70. Nothing further was heard of the patient until he was readmitted on March 3rd, 1919, with considerable œdema of the legs, and complaining of pain over the region of the liver.

On admission the apex beat was in the sixth intercostal space, five and a half inches from the middle line; the force of the impulse was feeble, the area of cardiac dullness was increased considerably to the left of the nipple line. At the apex systolic and diastolic bruits were heard; a diastolic bruit was also audible over the aortic cartilage. The patient was very breathless and complained of continual cough, and there were signs of congestion at the bases of the lungs. Pulsation was marked in the vessels of the neck, and considerable distension of the veins was observed; the radial pulse-rate was between 40 and 50. The patient vomited a good deal after admission and his cough was persistent and distressing; he was too ill to be thoroughly examined. The radial pulse-rate continued to vary between 30 and 50.

Irregular Heart Rhythm.

On March 28th the vomiting had ceased and the cough was better. Examination of the heart showed an irregular rhythm, two beats and then a long pause, and so on. Polygraphic tracings showed the second of the two beats to be well marked in the cardiogram, but very feebly marked in the radial tracing, the beat hardly getting through to the wrist. The first and second heart sounds were distinctly audible, corresponding to each of the two beats, and in the long pauses between the coupled beats a third and shorter sound was occasionally heard. (Fig. 1.)

No murmurs were now heard, the first sound being very short in duration. The patient remained in bed for many weeks, the radial pulse-rate varying considerably, being always slow on account of the failure of the second of the coupled beats of the ventricle to affect the pulse at the wrist, although in some of the radial tracings it could just be detected. He suffered from several syncopal attacks, and during these there was marked slowing of the cardiac rhythm, the radial pulse-rate falling as low as 30, the ventricular rate being double this. He never became completely unconscious, and never exhibited typical Adams-Stokes syndrome. Except for one emergency dose administered hypodermically on admission digitalis was not given. Injections of atropine were without appreciable effect.

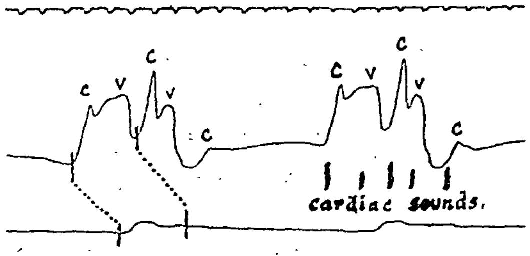

FIG. 1.—Cardiogram. J, jugular; R, radial.

During the last two weeks the œdema had been increasing, and on April 10th there was general anasarca; the swelling affecting the arms and hands and also the upper part of the chest. The pulse-rate had been increasing, and he had been passing very little urine. From this time onwards his condition became rapidly worse, the daily excretion of urine falling to a very few ounces. A few days before death the œdema markedly diminished. Figs. 2 and 3.

It was, unfortunately, not possible to obtain an electrocardiogram, the patient's condition being so grave that he could not be moved from his bed. The accompanying tracings were taken with a Mackenzie ink polygraph 18 days after admission. The arrhythmia is striking, and at first suggests the appearance seen in tracings from patients who have been for some time under the influence of digitalis, and have reached the toxic stage where the familiar coupling of the beats is observed. As has already been stated, however, digitalis was not given on the second occasion of this patient's admission, except for one emergency injection of digitalin, and there was no reason to suppose that he had been previously taking the drug outside the hospital. There is no sign of an *a* wave in any of the tracings, and the jugular pulse is of the ventricular type. It was concluded that the auricles were fibrillating, although the pulse did not at any time show the typical continuous irregularity. On both occasions of admission to hospital there was always an absence

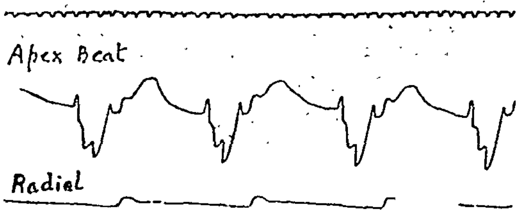

FIG. 2.—Inverted Cardiogram.

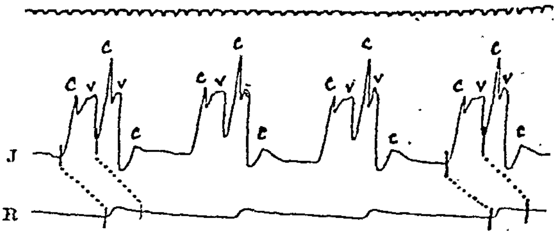

FIG. 3.—Cardiogram.
Pulse rate 32 (radial) Extra-systole not felt at wrist.

of any presystolic murmur at the apex, although the left auricle was greatly enlarged, and there was an extreme degree of mitral stenosis. The third of the *c* waves, which corresponded with the third sound already mentioned, is apparently due to a second premature contraction of the ventricle, which, although audible to the stethoscope, was never strong enough to affect the radial tracings. The first premature contraction, represented by the second of the *c* waves, can just be detected in places in the radial tracing, but could never be felt in the pulse at the wrist. From the character of the attacks of semi-unconsciousness and the extreme slowness of the pulse during some of these, the condition appeared clinically to resemble that of heart-block, but no evidence appears in the tracings of independent auricular contraction, and the *a.-v.* bundle was subsequently shown to be structurally intact.

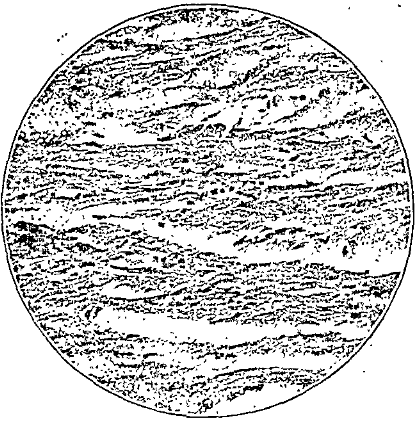

FIG. 4.—Microphotograph of a typical portion of the bundle.

Morbid Anatomy.

The heart as submitted for examination was enormously enlarged and weighed over 30 oz. The ordinary broad anatomical relationships were disturbed by a high degree both of hypertrophy and of dilatation. The area including the sino-auricular node had been destroyed in removing the specimen at the post-mortem examination, but since the pericardium was completely obliterated over the greater portion of its surface, and patches of lung tissue were adherent, its exact delimitation would have been difficult in any case.

Right Auricle.—Enormously dilated and accommodated the entire hand when closed. The tricuspid valve orifice admitted all four fingers and the thumb together. The flaps of the tricuspid valve were thickened by old inflammation and fibrosis.

Right Ventricle.—Greatly hypertrophied and dilated. Nothing was seen on naked-eye examination of the endocardium of the ventricle, pulmonary valves, or pulmonary artery, which called for comment.

Left Auricle.—Dilated, but not so much as the right. The mitral valve flaps were thickened and adherent to each other in the form of a rigid button-hole, admitting the tip of one finger. There were some patches of recent endocarditis on the edges of the valves covered with antemortem clot.

Left Ventricle.—Hypertrophied and dilated, the aortic valves were thickened, fibrosed, and incompetent. There were one or two small patches of recent endocarditis on the upper surface of the posterior cusp. The chordæ tendineæ were thickened in a degree corresponding with the state of the mitral valve.

Heart Muscle.—The heart muscle generally seemed softer than normal, and in cutting through the wall the larger branches of the coronary arteries were seen to be somewhat thickened and sclerotic. On microscopic examination a very slight degree of fatty change could be made out, and it was not easy to define cross striation in the muscle fibres in all the sections examined.

The adventitia of the vessels all over the heart was proliferated, and in the case of the moderate-sized vessels was generally the seat of collections of small round cells.

Auriculo-ventricular Node.—On cutting serial sections through the septum at the auriculo-ventricular junction, the auriculo-ventricular node was found to show an increased amount of fully-formed connective tissue, while the bundle, in order to reach the ventricular portion of the heart, had to pass through a dense mass of fully-formed connective tissue which was found in the upper portion of the interventricular septum. This had apparently been formed by a new growth of connective tissue, extending from the attachment of the septal flap of the tricuspid valve through the thickness of the septum until it coalesced with the right side of the central fibrous body. This latter structure was distorted by the general hypertrophy and dilatation; instead of being more or less triangular in section, as seen from above it was elongated into a thick band.

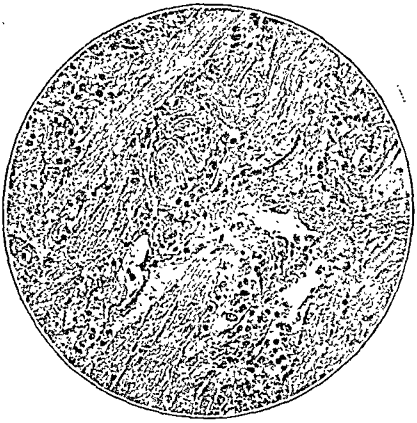

FIG. 5.—Microphotograph showing infiltration of leucocytes through the muscle.

Other Findings.

Neither in node nor bundle were any lesions seen of a definite character. The only abnormality found in these structures consisted of a few sparsely scattered small round cells, although the connective tissue in which the bundle was embedded for part of its course showed definite well-marked infiltrations of lymphocytes. A microphotograph of a typical portion of bundle is shown in Fig. 4.

One definite finding was the occurrence of infiltrations of lymphocytes all through both auricular and ventricular muscle, but better marked in the ventricle (Fig. 5). Many of these were associated with the overgrown adventitia of vessels, but in some cases they occurred apart from the vessels. The main artery of supply to the septum showed a high degree of sclerosis affecting the muscular coat.

There was slight ascites, but the peritoneum itself was normal. The liver was of the nutmeg type, showing fatty changes; the spleen was soft and showed the ordinary changes of passive congestion. The kidneys were congested and cloudy, the pancreas was normal. The stomach was considerably dilated and full of greenish fluid with particles of undigested food. The intestines were normal.

We are indebted to the courtesy of Dr. Collier for permission to publish some of the back notes of the case.

LYMPHADENOMA AND TUBERCULOSIS.

BY I. FOX, M.B., B.S. LOND.,
ASSISTANT PATHOLOGIST, BECK LABORATORY, SWANSEA GENERAL HOSPITAL.

MANY cases have been described in which tubercle bacilli have been found in the lesions of Hodgkin's disease. Generally these cases have shown locally a definite tuberculous lesion, clearly distinguishable from the lymphadenomatous process and often also from the appearance given by tuberculosis in organs not affected by lymphadenoma. Ziegler gives 20 per cent. as the proportion of cases of Hodgkin's disease which die of generalised tuberculosis. The generally accepted theory that such tuberculosis is a secondary infection is one which must remain to a certain extent on probation until the ætiology of Hodgkin's disease is established. In view of the emphasis which has been placed on the difference between the lesions of the two conditions, the following record seemed to be worth publishing, although the conclusions to be drawn from it are not very clear. In this case no gross tuberculous lesion was found post-mortem, the only macroscopic changes being those of Hodgkin's disease of abdominal type. In the affected glands and spleen tubercle bacilli were found in fairly large numbers, for the most part without other cellular reaction than one which appears to be that generally described as peculiar to Hodgkin's disease.

A Case Described.

The patient, a man aged 34, was admitted to the Swansea General Hospital under the care of Dr. F. Begg on Feb. 3rd, 1921, as a case of Hodgkin's disease. He had an indefinite history of severe anæmia and abdominal swelling for 12 months. On admission, he was obviously moribund. He was wasted; the skin was of an earthy colour; there was pyrexia, and the breathing was deep and rapid, suggesting acidosis. The spleen was greatly and the liver slightly enlarged. The inguinal glands on both sides were moderately enlarged and also one cervical gland. A blood count (Feb. 4th) showed: Hb. 15 per cent. (Sahli); r.b.c., 1,800,000; C.I., 0·38. The white count gave the very low figure of 630 per c.mm. Differential white count:—

Polymorphs ..	.. 67 per cent., or	423 per c.mm.	
Sm. lymphocytes	.. 29 ,, ,,	183 ,,	
Large ,,	.. 1 ,, ,,	6 ,,	
Large hyaline	.. 2 ,, ,,	12 ,,	
Basophile ..	.. 1 ,, ,,	6 ,,	
	100	630	

There was much poikilocytosis. One normoblast seen. Films showed numbers of Gram-positive cocci and short bacilli.

Post-mortem Examination.

The patient died on Feb. 5th, and a post-mortem examination was performed on the 7th by Dr. A. F. Sladden. The tissues were unusually dry; the amount of blood seemed reduced to a minimum, so that there was little decomposition in spite of a terminal septicæmia. No cultural examination of the organs was made. The brain and meninges appeared normal. The heart was dilated, pale, and flabby; the lungs moderately congested but showing no other abnormality. The large vessels were apparently normal and the thoracic glands were not enlarged. The liver was congested. The intestines showed no gross lesion; and, apart from pallor, no change was seen in the kidneys, pancreas, or suprarenals. The spleen was greatly enlarged, weighing 2¼ lb. It was firm, dark in colour, and somewhat uniformly and closely studded with pale yellowish-grey nodules, the largest being rounded and about ¾ cm. across. Some Malpighian corpuscles could be defined. There was no caseation and no nodule could be seen resembling a tuberculous focus. In addition to the enlarged inguinal glands large clumps were present in the external iliac, mesenteric, and lumbar groups. These glands all presented a similar appearance. Except for some ill-defined masses round the aorta, they were discrete and always pale, showing on section a greyish-yellow semi-translucent homogeneous substance, traversed gularly by fine paler lines. There was no suggestion seation or calcification in any gland. The bone ow was fatty, films showing scanty large mononuclear anular cells.

Microscopic Appearances.

Glands.—The loose periglandular tissue showed extensive recent fibrosis, with formation of a fine reticulum by budding fibroblasts. Various Gram-positive and negative bacilli and a few cocci were found. The gland vessels were greatly increased in number. Many were entirely or partially replaced by a cord of young fibrous tissue, others had their lumen reduced by the intramural formation of a fine reticulum containing numerous small channels lined by a single layer of flat endothelium. In one vessel the lumen was almost blocked by this reticulum, which here contained very large endothelioid cells, staining deeply with hæmatoxylin and greatly resembling "lymphadenoma" cells. A fungoid swelling composed of necrotic cells in a fine reticulum scantily invaded by fibroblasts invaded the lumen of another. Among the dead cells were large round pale cells, resembling the endothelioid cells of a tubercle. The adventitia at the base of the mass showed much loose reticulum formation. No tubercle bacilli were found.

Gland Substance.

The glands themselves were greatly altered, the lymphoid element having almost completely disappeared. Spread irregularly through the gland were a few areas only showing small lymphocytes in the pulp. The reticulum showed hypertrophy, the gland consisting of a meshwork of coarse and fine strands with numerous lined channels. There was slight transformation into fibrous tissue, but otherwise little fibrosis. Among the endothelial cells, the number of which varied greatly in different parts, were large phagocytes with several pale oval nuclei, often containing red blood cells, and some large deeply staining irregular cells with one or more dark nuclei. Throughout there was more necrosis than is typical of lymphadenomatous glands, but no massive death. Eosinophiles were scanty. Tubercle bacilli were found scattered irregularly in the glands. In one large colony in a lobe of the less nucleated type of reticulum there was considerable nuclear debris among the bacilli, but otherwise no more necrosis than elsewhere. Apart from the vascular conditions there was no lesion in these glands which suggested by its appearance a tuberculous process. No other bacilli or cocci were seen in the gland substance, and no polymorphs were present.

Liver.—Lymphoid tissue occurred freely along the vessels, which showed slight changes similar to those of the gland vessels. No tubercle bacilli were found.

Kidney.—Sections from two pieces showed little abnormality. No tubercle bacilli were found.

Spleen.—The main vessels showed the following changes. In the artery there was patchy hyperplasia of the intima, chiefly of the elastic element, and in other parts degeneration of the elastic fibres and fibrosis. The media showed some hypertrophy. The adventitia of artery and vein was the site of new vessel formation (many of these showing obliterative endarteritis) and round cell accumulation with fibrosis. The chief lesions of the spleen itself were essentially the same as those of the glands. The reticulum was greatly increased throughout and the Malpighian corpuscles rarely appeared normal. Almost always there was some proliferation of the endothelium of the central artery and sometimes the lumen was greatly diminished. There was often hyperplasia of all the coats of the vessel, sometimes fibrosis. The lymphoid tissue of the follicles was greatly diminished, disappearing apparently through hypertrophy of its own reticular element. There was much hypertrophy of the reticulum which was on the whole more cellular than in the glands. The pulp contained blood cells, degenerated blood, much pigment, and a great number of very large cells (12–40 μ) of two types. Many of these cells were crammed with degenerated red cells, and also contained polymorphs, eosinophiles, other endothelioid cells, and tubercle bacilli. These phagocytic cells generally had one or two oval, comparatively pale nuclei. The other type stained deeply with hæmatoxylin and showed a great variety of shapes. It had one (generally) or more large nuclei which stained intensely. Occasionally such a cell reached a diameter of 46 μ. Cell inclusions, except pigment, in these were rare. A few eosinophiles could be detected. The spleen also showed small infarcts: areas of extravasated red cells and fibrin, patched with areas of an empty fine reticulum, the whole being surrounded by congested tissue. Tubercle bacilli were found fairly uniformly distributed in the sections, usually singly, or a few together, often inside endothelial cells. In one of five blocks examined several colonies of bacilli could be picked out with the low power objective because of the amount of nuclear debris among which the bacilli lay. Apart from this appearance there was little, if any, more acute necrosis here than elsewhere in the spleen tissue and no special reaction of endothelial cells. There was also in the same block, near these colonies, a lesion which seemed to me undoubtedly of tuberculous origin, although no tubercle bacilli were found in it and there was no quite typical tubercle formation. It consisted of an irregular nodule near a fibrous trabecula. The nodule was a mass of round, greatly swollen and mainly necrotic endothelioid cells, exactly like those sometimes seen standing out from the lymphocytes in tuberculous glands. There was little fusion of these dying cells, but they, or their spaces, were well defined. A stroma of fibroblasts and fibrous strands was being formed between them. In one place a round cell accumulation, with capillary and fibroblast spread among the endothelioid cells, gave, apart from the absence of giant cells, a fairly typical picture of tuberculous granulation tissue. Large dark cells resembling those described above occurred here in small numbers. This focus was marked off to some extent from surrounding tissue by a congested and fibrous zone. Yet in spite of this localisation and the type of cell present, the lesion was not very different from the general one of the spleen and glands, and it greatly resembled that of one of the gland vessels.

Remarks.

In this case (clinically one of Hodgkin's disease) there are, then, lesions strongly resembling those of lymphadenoma and containing numerous tubercle bacilli. There is also a focus of tuberculous type, but not very characteristic, which showed some resemblance to lymphadenoma. The vascular conditions present might be due to either disease. If this case should be described as one of Hodgkin's disease, then, according to current theory, the tuberculosis is a secondary infection. Tuberculosis terminates many cachectic conditions, but does not, as a rule, select the tissue which is the chief site of the primary disease. In this case, since the abdominal glands of an adult are affected, the selection is more apparent that it would have been in a case of cervical or mediastinal lymphadenoma with tuberculosis. The obvious tuberculosis found post mortem in cases of Hodgkin's disease may have more significance than appears. For one cannot but believe that, if this man's blood destruction had not been so acute, he must have died before long from generalised tuberculosis. If he had the abdominal glands and spleen would hardly have been regarded as the original stronghold of the tubercle bacillus. With regard to the ætiology of lymphadenoma, the terminal septicæmia of this case may possibly be of significance, although the various bacteria found in sections were not specially related to the lesions.

It seems just possible that in deciding against a connexion between the tubercle bacillus and lymphadenoma too much emphasis has been placed on negative results of inoculation experiments. But even if we admit that a true lymphadenoma, not caused by the tubercle bacillus, exists it may well be that the term at present is applied to more than one disease, perhaps including a primary tuberculosis. In the case described above, on histological grounds a diagnosis of atypical tuberculosis seems possible, although it leaves the toxic factor unaccounted for. If this case is not true lymphadenoma, it is yet not without interest in relation to the problem of the ætiology of that disease and its relation to tuberculosis.

I should like to express my indebtedness to Dr. Sladden for much help in investigating the case.

A COURSE IN HELIOTHERAPY.—A clinical course of lectures and demonstrations on heliotherapy will be given at Leysin from August 16th–20th by Dr. A. Rollier and his assistants. An invitation to attend will be sent to any medical man or woman expecting to be in Switzerland, on application to the Secrétariat Médicale du Dr. Rollier, Leysin, Switzerland.

CONFERENCE ON INFANT WELFARE.—An alteration has been announced in the programme of the Second English-speaking Conference on Infant Welfare summarised in THE LANCET of June 18th last (p. 1330). The special medical session, 5.30 to 6.30 P.M., on Wednesday, July 6th, will be devoted to a discussion on "The Uses and Abuses of Dried Milk," to be introduced by Dr. Harold Scurfield, formerly M.O.H. for Sheffield. Various minor alterations of and additions to the programme are also announced.

Medical Societies.

BRITISH CONGRESS OF OBSTETRICS AND GYNÆCOLOGY.

THE first British Congress of Obstetrics and Gynæcology was held in Birmingham on June 3rd and 4th, the following societies taking part in the meeting: Royal Society of Medicine (Obstetrical and Gynæcological Section), Edinburgh Obstetrical Society, North of England Obstetrical and Gynæcological Society, Glasgow Obstetrical and Gynæcological Society, and Midland Obstetrical and Gynæcological Society.

Mr. CHRISTOPHER MARTIN, as President of the Midland Obstetrical and Gynæcological Society, extended a hearty welcome to the visiting societies, and expressed the hope that the Congress would be so successful as to warrant it becoming an annual affair, and the most important meeting of the year for those whose chief aim was the furtherance of British obstetrics and gynæcology.

Dr. EWAN MACLEAN (Cardiff) called the attention of the meeting to the resolution which Prof. W. E. Fothergill and Dr. F. H. Lacey proposed to move—viz., "That in the opinion of this meeting, operations by the abdominal route are quite unnecessary for the treatment of genital prolapse." He thought that the best interests of the profession would not be served by placing this resolution before the meeting, and he proposed that Dr. Fothergill be asked to withdraw it.—Dr. HERBERT SPENCER seconded Dr. Maclean's motion, which was carried, and Dr. Fothergill subsequently withdrew his motion.

Dr. FOTHERGILL, in an opening paper to a discussion upon the

End-Results of Vaginal Operations for Genital Prolapse,

said that the discussion had originated at a meeting of the North of England Society held at Liverpool in December, 1918. Prof. H. Briggs had described the treatment of a case of procidentia in a patient, aged 18, by a vaginal operation combined with ventrofixation. Dr. W. Blair Bell deprecated ventrofixation but advocated a modification of Gillian's operation. Dr. Fletcher Shaw deprecated abdominal operations for prolapse, preferring the vaginal methods used in Manchester. Owing to the divergent opinions expressed, it was suggested that the end-results of these measures should be ascertained and a collective investigation by the Society was proposed. The term "genital prolapse" had a fairly definite connotation all over the world; and medical men constantly use the word "prolapse," as including both so-called vagino-uterine prolapse, and so-called utero-vaginal prolapse. In view of these considerations it was decided at a council meeting of the North of England Society in December, 1919, that the inquiry should include "cases of (1) cystocele, (2) rectocele, (3) prolapsus uteri, and (4) elongated cervix protruding from the vulva." In October, 1920, Dr. F. H. Lacey gave a preliminary report on traced cases operated on at St. Mary's Hospital, Manchester, during the years 1914–15–16. It was arranged, however, to defer further consideration of the subject until the present Congress, in order to obtain the views of British gynæcologists as a whole.

Dr. Fothergill then briefly indicated the steps by which he was led to adopt the technique which he now uses, and paid tribute to the work of the late Sir A. H. Simpson, the late Berry Hart, and especially that of Prof. A. Donald of Manchester. In 1895, owing to the initiative of Donald, the surgical treatment of genital prolapse was already highly evolved and most efficient. For the last 30 years Donald has operated in hospital four days a week and has cured an enormous number of cases of prolapse by amputation of the cervix, extensive anterior colporrhaphy and his own colpo-perineorrhaphy. The speaker's contribution to the subject was first made in 1907 before the Royal Society of Medicine, when he drew attention to the importance of the parametrium and paracolpos in supporting the uterus, vagina, and bladder. In 1908, before the Edinburgh Obstetrical Society, he pointed out the importance of suturing the parametrium in front of the cervix in the treatment of prolapse. Subsequently he had found that by carrying the incision of anterior colporrhaphy round behind the cervix instead of in front of it, this operation and amputation of the cervix could be conveniently combined in a single step. This operation was demonstrated to graduates at the Manchester Royal Infirmary in March, 1913, and in 1915 the improved technique was described and figured.[1]

The inquiry which he and Dr. Lacey had instituted as to the results of this operation had resulted in 156 replies covering a period of from 4½–7½ years from the date of operation. 150 women stated, without qualification, that they were cured, whilst 6 did not. Of the failures, 2 were subsequently found on examination to be anatomically free from prolapse, giving a total of 97 per cent. cures. As to the age of the patients, one-third had passed the menopause. The combined amputation of the cervix with anterior colporrhaphy had been done in 124 cases. Since their operations, 21 of the women under 40 and 3 of those over 40 have had children and 2 are now pregnant. Of these 26, no less than 23 had had the cervix removed, showing that the operation had failed to prevent pregnancy in nearly a quarter of the women of reproductive age. Thirty children had been born to the 24 patients, and in no case had labour been obstructed. Twenty-three of the confinements were natural, and in seven only were forceps required. Four patients had had two labours with no recurrence of the prolapse, and 17 had had one labour with no recurrence. Dr. Fothergill, in conclusion, observed that, inasmuch as vaginal operations afford for all varieties of prolapse treatment that is efficient and permanent, that does not prevent pregnancy and that stands the test of parturition, in a large proportion of cases, abdominal intervention is unnecessary and undesirable. The latter adds to the risk and discomfort of the patient and involves more trouble and loss of time to the operator.

Genital Prolapse treated by Vaginal Operation.

Dr. F. H. LACEY (Manchester) read a report upon an investigation of 750 patients admitted to St. Mary's Hospital, Manchester, during the years 1914–15–16, suffering from genital prolapse and treated by vaginal operation. The patients were women of the working class, who in many cases were compelled to return to the cotton-mill, munitions, or other heavy work at a short interval after their return home. The figures given consist of the average of all the surgeons on the hospital staff, of whom there were 10 in number, including resident surgical officers. A letter was sent to each patient asking the following questions: (1) "Does the womb keep up well now?" (2) "Have you had any confinements since the operation?" (3) "If so, how many?" (4) "Did you need instruments at any of these confinements?" (5) "Has the womb come down at all after any confinement since the operation?" 521 replies were received, and of these, 455 (87 per cent.) answered the first questions with an emphatic "Yes." Twenty-nine were "improved" but not cured. Twenty-six replied that the operation had not been successful. Of the women of reproductive age. 330 successes bore 67 children (20 per cent.). Instruments were required in 32 per cent. of these. Nineteen "improved" cases bore 6 children (31 per cent.). Thirty-three ures bore 16 children (48 per cent.). These results make it probable therefore that subsequent labour was in many cases the cause of the failure of the operation. One death had occurred during the period under investigation, the cause being pulmonary embolism. Dr. Lacey was of opinion, from a consideration of the figures obtained, that it was unnecessary and superfluous to operate for genital prolapse by the abdominal route, as well as submitting the patient to increased risk.

Prof. ARCHIBALD DONALD (Manchester), continuing the discussion, read a

Short History of the Operation of Colporrhaphy, with remarks on the Technique.

He expressed the opinion that colporrhaphy, in the proper sense of the word, has been more frequently done in Manchester than in any other town in this country. In 1884–87 as a resident surgical officer to St. Mary's Hospital, Manchester, he had been struck by the large number of women attending the out-patient department suffering from serious degrees of prolapse and treated by the insertion of pessaries, some of enormous size. He was of opinion that operative treatment on lines similar to the cure of hernia ought to be possible and successful. When he was appointed surgeon to the hospital in 1888 there was little published in this country to encourage anybody to attempt the operations advocated in America and Germany for the treatment of prolapse. His first operation was undertaken in 1888 for a large cystocele in a woman aged 48. He removed a diamond-shaped area of vaginal mucous membrane from the anterior vaginal wall and the surfaces were approximated by a spiral of continuous catgut in "étage." At his second operation in 1888 the cervix was amputated as the first stage, silver wire being used for the first and last time to approximate the cervical flaps. Anterior and posterior colporrhaphy followed. The posterior colporrhaphy was done in stages from above downwards, a large triangular area of posterior vaginal wall being removed, the apex of the triangle being close to the cervix. The results of these and later cases finally established in the speaker's mind the value of colporrhaphy, but for three or four years he turned his attention to operations for the suspension and fixation of the uterus through the abdomen. He was never satisfied with these in cases of prolapse, and he returned to the vaginal operations, which he had never entirely discarded. For a time vaginal fixation as part of the vaginal operation was practised, but this was abandoned after a few years.

Subsequently, the number of colporrhaphy operations at St. Mary's Hospital greatly increased with changes in the staff, and Walls, Fothergill, Clifford, and Fletcher Shaw have all given practical proof of their faith in the operation as a curative measure. To-day the vaginal route is entirely employed by Dr. Donald in the treatment of prolapse, and he regards buried sutures as one of the most important points in the operation, the continuous "blanket stitch" in the deep tissues being employed. With the aid of a Reverdin needle and the help of a trained assistant the whole operation (amputation of cervix, anterior colporrhaphy, and posterior colpo-perineorrhaphy) can be completed in 30 minutes. In conclusion, the speaker observed that in his opinion there is no operation in which one can guarantee with more confidence a good result than colporrhaphy for vaginal and uterine prolapse.

Dr. HERBERT SPENCER (London) observed that statistics have been described as "lies expressed in terms of figures." He was not able to put forward figures himself, but on the whole he could say that he was fairly well satisfied with vaginal operations for prolapse, and he agreed with Dr. Fothergill that abdominal operations were not necessary. The figures that Dr. Fothergill and Dr. Lacey had given included moderate cases as well as severe, and it must be remembered that any of the various methods advocated are very likely to cure these slight degrees of prolapse. Dr. Spencer showed a specimen of a uterus the seat of carcinoma and fibroids, which had been completely prolapsed and which he had removed by vaginal hysterectomy. Some cases of severe complete prolapse he thought could only be cured by vaginal hysterectomy. With regard to Dr. Donald's paper, he observed that operations of a wide plastic nature had been performed in this country in the cure of prolapse since 1883, to his knowledge, and by himself since 1887 at University College Hospital. He was sure that Dr. Donald's method was a good one, but personally he did not use catgut because of certain risks. He employed buried silk sutures as a general rule, and occasionally buried silkworm-gut in old patients. As regards Lefort's operation he had done it a few times, but was not favourably impressed with the method.

---

[1] erican Journal of Surgery, May, 1915; Journal of ies and Gynæcology of the British Empire, March–May,

Dr. T. G. **STEVENS** (London) expressed his great indebtedness to Drs. Donald and Fothergill of the Manchester School for all that they had given to the gynæcological world in the matter of treatment for genital prolapse. In London he felt that they had lagged far behind Manchester in this respect. Since 1913 he had followed very closely the teaching described, and he was absolutely convinced that the methods advocated were the best up to date. If failure results it is due as a rule to the patient getting up or working too soon after the operation. Personally he always employed catgut buried sutures in the deep tissues and had found that buried silk or silkworm gut often led to delayed suppuration. Catgut nowadays was fairly reliable, especially if a mild chromacised gut was used. Dr. Stevens also drew attention to the risk of secondary hæmorrhage after Dr. Fothergill's operation. In one or two cases it had been very severe, and came from vessels just below the cervical mucosa. He thought that it was due to spreading apart of the tissues and not to suppuration. He was of opinion with regard to end-results that moderate cases of prolapse do not give quite so satisfactory a cure as severe ones, probably because the operation is not so severe. Also he found that the worse the procidentia the easier it was to cure, because of the ease of obtaining plenty of parametrial tissue. Abdominal operation, in his opinion, played no part whatever in the treatment of prolapse.

Dr. A. E. **GILES** (London) expressed his appreciation of the figures and results brought forward by Dr. Lacey and referred to the amount of labour required in furnishing such a report. A criticism that he would offer was that it was impossible to gauge the result of an operation by patients' statements. Symptomatic cures were often not anatomical cures. He had noted with interest that amongst the symptomatic failures quoted by Dr. Lacey were several anatomical cures. The converse might also be true. No operation could be curative in *every* case, and for this reason the result should not be guaranteed. In his experience 96–97 per cent. of cases were cured after operation. His practice followed mainly that of his old teacher, Prof. Donald, but he did not think it necessary to amputate the cervix in every case, as the cervix will return to its normal size. He had seen many cases where the cervix had been removed by various surgeons, and in some the results were atrocious. Amputation of the cervix was, however, justifiable in hyperplasia of the vaginal portion in nulliparæ. With regard to Dr. Fothergill's operation he thought that to say it was the *only* method was rather begging the question. There were over 150 different methods of suturing the abdominal wall and one writer had stated that every one was as good as another. In the same way he could claim equally good results in the treatment of prolapse from hysteropexy combined with a vaginal plastic operation.

Dr. J. E. **GEMMELL** (Liverpool) stated[2] that the total number of cases operated upon by him at the Hospital for Women, Liverpool, from the year 1902 to December, 1917, was 480, that of these 172 had been traced, and that the length of time since the operations varied from 3¼ to 15 years, averaging 7 years. The methods of treatment employed were anterior colporrhaphy and posterior colpo-perineorrhaphy (40), interposition operation (27), and anterior and posterior colpo-perineorrhaphies plus ventro-fixation (105). The last-named is used in young women during the fertile period, because the vaginal work may be restricted to moderate removal of tissue; an additional fibro-muscular ligament is introduced, conception and parturition are not affected, and the method of operation stands the test of subsequent parturition. Of the 105 cases so treated 30 had borne children and there had been no return of prolapse. The speaker described in detail his method of performing ventro-fixation.

Dr. **WALTER SWAYNE** (Bristol) described, with illustrations, the method of operation which he had evolved and which very closely followed that of Dr. Fothergill. He reconstructed as far as possible the original pelvic supports, paying special attention to the ligaments of Mackenrodt or Patterson. A cystocele he regarded as a hernia through the anterior part of the fascia covering the vaginal wall. Similarly a rectocele was a hernia through the posterior part of the fascia of the vaginal wall. His experience exactly coincided with that of the Manchester School, and he was averse to abdominal methods. Anatomically they are not correct procedures. The question raised by Dr. Giles as to the difference between anatomical and symptomatic cures was an interesting one, but after all it appeared to him to be a minute point. Deal with the case by all means on anatomical principles if possible, but above all relieve the patient of her symptoms. He had not had the pluck so far to perform a very severe operation upon women of child-bearing age, and he was of opinion that if it was done the patient should be warned that the result might be marred by a subsequent labour. He had had some experience of Dr. Blair Bell's procedure, but anatomically it seemed to be unsound, although it relieved symptoms.

Dr. C. D. **LOCHRANE** (Derby) observed that during the past few years he had recorded his results of 350 cases of genital prolapse, but had kept an open mind and given each operation published a fair trial. He thought that the ideal operation should conform to four principles: (1) it should restore the parts as far as possible to the normal condition; (2) it should be applicable to all types of injury and at all periods of life; (3) it should not interfere with pregnancy or cause dystocia; (4) it should be the least dangerous, and, as an addendum, the simplest and cheapest. The operation which conformed in his experience nearest to these axioms was the vaginal plastic method and not any abdominal technique, and during the last six years he had treated less and less cases by the abdominal route and more and more by the vaginal. Although he had never seen dystocia arise from ventral fixation, he had had several cases of recurrence of prolapse following the operation. With regard to the vaginal method he considered that previous preparation of the patient, especially as to sterilisation of the vagina, was most important and should be undertaken three or four days before the operation. Whenever he thought that sepsis was likely his practice was to apply bismuth-iodoform-paste to the tissues previously. When amputation of the cervix was required, he preferred Bonney's technique to the circular method. Further, he never employed buried sutures, but always used a figure of 8 stitch to the perineum.

Prof. **HENRY BRIGGS** (Liverpool) drew attention to the importance of not losing sight of general principles in an unbounded enthusiasm for any one method, and entered a protest against what he could only think were the exaggerated and incorrect statements of some of the speakers. It was incorrect to think that one method only could cure prolapse, or that one type of suture material, such as catgut, was the only material admissible. It was very difficult to get at the true facts of the case, just as it was to believe the statement of a man who says that he never gets an incisional hernia after an abdominal operation.

---

[2] See also THE LANCET, June 18th, p. 1291.

Dr. **W. S. A. Griffith** (London) referred to cases of prolapse of the vaginal walls following a previous hysterectomy. He personally had had extreme difficulty in dealing satisfactorily with this type of case, and was of opinion that no operation by the vaginal route, short of obliteration of the vagina, could be successful. The abdominal route was perhaps indicated for cases such as these. With regard to the points raised by other speakers, he believed in buried sutures and a wide anterior colporrhaphy in treating ordinary cases of genital prolapse. Retroversion and retroflexion of the uterus per se did not often cause symptoms unless the ovaries were also prolapsed, when operative treatment might be required.

Dr. **R. H. Paramore** (Rugby) drew attention to the complete absence in the case of previous speakers to any reference to the levator ani musculature in the cause of genital prolapse. He was under the impression that myorrhaphy of the levatores ani was important, and was surprised that no mention had been made of this procedure. His own experience was limited to 11 cases, and of these he only could claim one success. In all the others, separation of the levatores had occurred two to three weeks after operation. The speaker referred to Hey Groves's suggestion of separation of the anterior vaginal wall from the urethra, and also to Cuthbert Lockyer's method of dissection of the levatores ani. His own conception of prolapse was that it was a hernia through the pelvic fascia, and he attempted to narrow the ring by cutting down upon the levatores ani, drilling holes through the pubic arch, and approximating the margins of the muscles joining the pelvic diaphragm by a purse-string suture.

Prof. **Gammeltoft** (Copenhagen) expressed surprise at not having heard greater reference to the levatores ani. His method of treating prolapse was first to perform a wide anterior colporrhaphy, as is done at Manchester. Then he dissects the levatores ani and approximates these muscles. He always uses catgut, and has never seen any of the bad results attributed to it. He did not use abdominal operations for prolapse, or agree with them.

Dr. **J. S. Fairbairn** (London) referred to the difficulty of knowing exactly how much tissue to remove in vaginal operations for prolapse in order to avoid an excessive amount of narrowing of the vaginal canal. On one occasion he had, as a matter of fact, completely occluded the urethra, and subsequently had to remove his sutures. He did not remove the cervix in the percentage of cases described by Dr. Fothergill, and could not quite see the necessity for it. He also drew attention to the possibility of secondary hæmorrhages referred to by other speakers, and he himself had had several instances. With regard to the question of anatomical versus symptomatic cures, he would note that there was no fixed anatomy. The cure should be physiological, and, if so, anatomy would not count.

Mr. **Furneaux Jordan** (Birmingham) stated that for many years he used ventral fixation combined with colporrhaphy, anterior and posterior, but the results from the vaginal plastic operation were infinitely better. A few years ago he had seen Dr. Fothergill operate, and he was so impressed by the method that he had always employed it since. It was a tribute to the operation that since he had used it he had had more gratitude from his patients than from all his previous cases. He was quite sure that the operation could not be done without burying sutures, and if it was proved that catgut is not safe, it should not be employed for this purpose.

Dr. **Miles H. Phillips** (Sheffield), as a pupil of Prof. Donald and Dr. Fothergill, had in large sure adopted their practice. At the same time he ld not assert that he had cured *all* his cases, and lered if any one method would cure all. The type of case where he failed was the elderly woman with complete prolapse of a small atrophied uterus. In these cases it is impossible to repair the vagina satisfactorily, and he used Mayo's operation of removing the uterus, obliterating Douglas's pouch and suturing the broad ligaments below the bladder.

Dr. **T. W. Eden** (London) was glad that Dr. Fothergill had withdrawn his resolution. He thought that perhaps he had tried to devise an operation for *every* case of prolapse. There were a few cases, however, where this was not possible, and where Mayo's operation is good and indicated for choice. It was important, therefore, that we should adhere to the principle of selecting the ideal operation for each individual case. For example, the treatment of prolapse in young nulliparous women occasionally offers extreme difficulty. He recalled such a case in which he had performed an extensive posterior colporrhaphy. The procidentia recurred, and Dr. Cuthbert Lockyer did a ventral fixation. The condition again recurred, and Dr. Eden had recently carried out the operation suggested by Blair Bell of obliterating Douglas's pouch by suturing together the utero-sacral ligaments. The anteversion of the uterus so produced he considered to be important. With regard to Dr. Fothergill's method, he was of opinion that the operation might be improved by associating it with wide separation of the bladder from the cervix, as originated by Cuthbert Lockyer.

Dr. **W. H. Newnham** (Bristol) observed that in Bristol the abdominal route had been practically abandoned entirely in favour of the vaginal operation for prolapse of vagina and uterus. Personally he always had used silk for buried sutures, and had seen no suppuration which he could attribute to its use. Nobody was infallible, and therefore no man could always guarantee a cure, whatever operation was undertaken.

Replies to the Discussion.

Prof. **Fothergill**, in reply, said that he had never seen or heard of any disastrous cases of secondary hæmorrhage following the vaginal operation. Undoubtedly it occurred, but it could always be controlled, and he attributed it to sepsis. With regard to interposition of the uterus, he thought it a bad operation. It was attended by some mortality and a large proportion of unpleasant sequelæ, to say nothing of recurrences. He had not mentioned suture of the levatores ani muscles, as he considered it a minor part of the operation. It was always done in Manchester, and was included under the term, "repair of the perineum." He quite agreed that some of the most difficult cases were those of prolapse of the vagina following hysterectomy. In young women, also, the operation could be very difficult.

Dr. **Lacey**, in reply, said that in Manchester no special preparation of the patients was undertaken. The women were admitted 24 hours before operation, and simply had a douche of cresol or perchloride of mercury. The vulva was covered by a perchloride-soaked gauze pad. He could not understand how Dr. Lochrane achieved his results without burying his sutures.

Prof. **Donald**, in reply, thanked Dr. Stevens for his very kind remarks. With regard to vaginal plastic operations for prolapse, there was no doubt that hæmorrhage did occasionally occur, and it spoilt one's operation. He employed a deep figure of 8 suture to control it, and amputated the cervix by Bonney's method. As to the operation described by Dr. Gemmell, he would like to note that it was originated by the late Sir J. Sinclair. Dr. Miles Phillips had drawn attention to the possibility of subsequent prolapse of the pouch of Douglas. In reply he would say that if colporrhaphy is carried sufficiently high it cannot occur. With regard to hysterectomy as a cure for prolapse he could not speak in favour of it, and had seen no more deplorable cases than those of prolapse of the vaginal walls containing coils of intestine occurring subsequently to vaginal hysterectomy. Again, as to the question of whether the uterus is subsequently anteverted or retroverted, he did not think that it mattered at all as long as it did not prolapse.

This concluded the business of the morning session. At 1 P.M. a lunch took place at the Queen's Hotel to members of the visiting societies, at the invitation of the members of the Midland Obstetrical and Gynæcological Society.

Condition of Sutures after Cæsarean Section.

At the afternoon session, with Dr. CARLTON OLDFIELD, President of the North of England Obstetrical and Gynæcological Society, in the chair,

Dr. CLIFFORD WHITE (London) showed two uteri removed at varying intervals after Cæsarean section, to show the condition of the linen-thread sutures. Dr. White referred to the recent discussions on rupture of the Cæsarean section scar opened by Mr. Eardley Holland and Dr. Munro Kerr, when the opinion was expressed that a non-absorbable suture gave the most firm union in the wall of the uterus after Cæsarean section, and that if a non-absorbable suture was used any weakness of the scar was the result of sepsis. The speaker brought forward the specimens to prove that, although he considered a linen-thread suture by far the best to employ in suturing the uterus, it was not ideal, one of its defects being that it may subsequently work its way towards the endometrium and cause menorrhagia, acting like a seton. The first specimen demonstrated the results of infection of stitches, and the resulting weak scar, which consisted almost entirely of peritoneum. The uterus was removed from a primigravida, aged 24, on the twelfth day after Cæsarean section for pelvic contraction, the patient having been 30 hours in labour. Intestinal obstruction developed from adhesion of three loops of gut to the edges of the abdominal incision and one coil to the uterine incision. The linen-thread sutures were lying loose on the peritoneal surface, and had cut through the whole of the wall of the uterus except its peritoneal covering. The case had run practically an afebrile course throughout. The patient made a good recovery after hysterectomy and free drainage. The second specimen was removed 17 months after Cæsarean section performed for labour obstructed by a cervical fibroid. The fibroid was not removed at the original operation, owing to the condition of the patient, who had been in labour 20 hours. Subsequent to the operation she complained of pelvic pain and menorrhagia. Hysterectomy was performed, and the uterus after removal showed a fibroid measuring 9 by 6 by 6 cm. in the cervix, just above the external os. The muscular wall of the uterus was firmly united in its whole thickness, but linen-thread sutures were appearing through the endometrium. Several could also be seen deeply embedded in the muscular tissue.

Dr. EWAN MACLEAN showed a specimen of a uterus removed four months after Cæsarean section, performed for obstructed labour, due to an intramural fibromyoma, and persistent transverse position. The uterine wall had been originally sutured with interrupted stitches of No. 4 silk, hysterectomy not being possible at the time owing to the patient's general condition. Section of the uterus after the second operation showed the uterine wall well healed. Microscopically, one of the suture sites on examination showed well-marked areas of round-celled infiltration as the result of the continual presence of the foreign irritant. Phagocytes were also seen. Section of the uterine wall, at the request of various members of the congress, was performed, and showed the silk sutures in situ without any absorption.

Dr. WALTER SWAYNE referred to a case of vesical calculus occurring in his practice after the use of silk sutures in a pelvic operation. He thought it probable that the bladder had been wounded on this occasion. His present technique always involved the use of catgut ligatures.

Dr. E. O. CROFT (Leeds) stated that he had had some experience of examining uteri after Cæsarean section had been performed, and he had found the whole of the silk absorbed. He also had had a case of vesical calculus following operation, but he still employs silk as a suture material, and gets good solid union. He believed that it was *slowly* absorbed, but its great value in Cæsarean section is that it persists until the uterine wall is healed.

Dr. HERBERT SPENCER was glad to hear this eulogy of silk for sutures. With regard to its disappearance, he had noted it on occasion completely to disappear in three months. On the other hand, he had known it persist for 17 years. Patients undoubtedly differ in this respect. He advocated silk of the "floss" type, and fairly thick sutures should be used. On only one occasion had he seen any adhesion of omentum or intestine to the scar.

Dr. EARDLEY HOLLAND (London) said that he had nothing new to add to what he had stated a year ago, when he thought that he had proved that cat-gut was not the best suture material for the uterine wall, owing to the risk of subsequent rupture. Mild sepsis could arise without any evidence of clinical value, as in one of Dr. Clifford White's cases.

Dr. MILES H. PHILLIPS did not believe that silk was ever absorbed.

Mr. FURNEAUX JORDAN thought that, theoretically, silkworm gut was the best material to use, and his views coincided with those of Dr. Eardley Holland.

Dr. EWAN MACLEAN exhibited a specimen showing

Combined Fibromyoma and Carcinoma of the Uterus,

removed from a multipara, aged 53. Pelvic pain of indefinite duration and irregular uterine bleeding of six months were the outstanding features. Total hysterectomy was performed, and the uterus showed a large cervical fibroid, 4½ inches diameter, and an advanced carcinoma of the corpus uteri. The speaker observed that in 500 cases of fibromyoma uteri which he had treated he had only noted concurrent carcinoma in two cases, 0·4 per cent. Kelly and Cullen in 1400 cases had found cancer of the uterine body in 1·78 per cent., and of the cervix in 1·28 per cent.

Dr. HERBERT SPENCER was surprised to hear that Dr. Maclean had met with so few examples of concurrent fibroids and carcinoma uteri. He had seen many cases and, in fact, many years ago read a paper advocating total hysterectomy in cases of fibroids on account of this very risk. He had noted six examples of unrecognised and early carcinoma in 200 cases of fibroids.

Dr. F. EDGE (Wolverhampton) had had six cases of carcinoma of the cervix in one year, subsequent to subtotal hysterectomy, and was of opinion that Dr. Herbert Spencer was right in his contention.

Dr. J. S. FAIRBAIRN's experience differed from the previous speakers, and he thought that the combination was very rare. He had only met with one example, and he reserved the right of performing subtotal or total hysterectomy for fibroids, as circumstances demanded.

Dr. HAROLD CHAPPLE showed a specimen which he considered to be a

Full-term Ovarian Pregnancy,

removed in March, 1921, from a patient, aged 33. The patient's last menstrual period occurred from Feb. 29th to March 3rd, 1920. Fœtal movements were felt in September, 1920, but had ceased since November, 1920, when there was a rather indefinite history of false labour. When the woman was examined on March 2nd, 1921, a tense cystic abdominal swelling was present. The fœtus was not definitely palpable, and no uterine contractions, uterine "souffle," or fœtal heart was audible. The uterus lay on the right side of the tumour and was not enlarged. At operation the tumour was densely adherent to many abdominal structures—transverse colon, omentum, for example. The left ureter passed over the antero-lateral aspect of the mass, and the corresponding round ligament lay in front. The left Fallopian tube was cut at the uterine attachment, and could be traced over the surface of the gestation sac. The uterus and right appendages appeared to be normal.

Professor GAMMELTOFT asked whether an X ray examination of the patient had been made previous to operation.—The reply was in the negative.

Dr. CUTHBERT LOCKYER (London) suggested that the specimen might be a tubo-ovarian rather than purely an ovarian pregnancy.

Dr. HERBERT WILLIAMSON (London) suggested that the specimen be referred to the Pathological Committee of the Section for detailed examination and report.

The proposition was accepted, and upon the proposal of Dr. THOMAS WILSON (Birmingham) the pathologist already at work upon the specimen will be invited to join the Committee.

Dr. GILES proposed that the report of the pathologist be received before the Committee met. This was eventually agreed to.

Dr. GILBERT I. STRACHAN (Cardiff) showed

Microscopical Preparations of an Early Ovum,

computed as being 16 to 18 days old. The specimen was obtained as the result of an abortion in a patient who had not missed a menstrual period. The ovum was discovered in a mass of blood-clot, passed per vaginam, and subsequently examined in detail. The small chorionic sac, about the size of an average index finger-nail, was hardened before section. Microscopically, the gestation sac shows amnion and well-marked chorionic villi. The section shown was taken through the cephalic flexure, and showed the early differentiation of the nervous matter into grey matter and white matter.

Dr. F. J. BROWNE (Edinburgh) read a communication upon

The Pathology of Syphilis of the New-born.

The paper was based upon the detailed macroscopic and microscopic investigation of 35 syphilitic fœtuses, and was illustrated by lantern photographs of the different viscera. The speaker drew attention to the failure of the Wassermann reaction in the diagnosis of fœtal syphilis, since on many occasions it is repeatedly negative in both mother and child when undoubted evidence of the disease exists on pathological investigation of the organs. The viscera which give most important evidence are the liver, spleen, kidney, suprarenals, and lung. The placenta may or may not show lesions, and Dr. Browne had been unable to demonstrate the presence of the *Spirochæta pallida* in any of the placentæ that he had examined. The speaker then described in detail the appearances which are diagnostic of syphilis in the various fœtal organs.

Dr. CARLTON OLDFIELD (Leeds) thought that one very important fact which had resulted from Dr. Browne's paper was that the diagnosis of syphilis as a cause of stillbirth cannot be made without a very exhaustive investigation.

Professor GAMMELTOFT agreed with Dr. Browne that neither examination of the placenta nor the Wassermann reaction can be relied upon in the diagnosis of fœtal syphilis. He considered, however, endarteritis of the vessels of the umbilical cord was a very important diagnostic point.

Dr. EARDLEY HOLLAND congratulated Dr. Browne upon his excellent paper. Personally he had been interested for some time in the stillbirth problem, but his investigations had been confined to viable and not macerated fœtuses. The problems he had set out to investigate were two—viz., the incidence of fœtal syphilis as a cause of stillbirth and how to diagnose syphilis in the absence of spirochætes. Formerly the percentage of fœtal deaths due to syphilis was thought to be as high as 50. Lately, wever, it has been proved by Whitridge Williams others that 15 per cent. is nearer the mark. own investigation in 37 cases had been con- to the following points: (1) the Wassermann reaction in the mother, (2) the presence of chondro-epiphysitis in the fœtus, (3) enlargement of the liver, (4) enlargement of the spleen, (5) examination of the placenta. In the case of the Wassermann reaction he had found it positive in the mother in 97 per cent. of the cases investigated. Chondro-epiphysitis was also present in 97 per cent. of the fœtuses. The spleen was enlarged in every case and the liver in nearly all cases. A difficulty arose with regard to the weight of organs, in that there is at present no absolute standard. It was necessary to consider, therefore, the ratio of the weight of the liver and spleen to that of the fœtus, and this is the line he is now taking. If both organs are enlarged, Dr. Holland considered it a very important diagnostic point. The largest spleens occur in cases of general œdema of the fœtus. As regards the placenta, naked-eye appearances are of no value. Typical microscopic appearances, however, were present in 67 per cent. of the cases examined. In all these, spirochætes had been demonstrated in the tissues. In the case of 263 still-born fœtuses where spirochætes could not be found, 25 were considered worthy of detailed investigation. Five of these showed certain evidence of syphilis, in spite of the apparent absence of spirochætes.

Dr. G. I. STRACHAN agreed with Dr. Browne as to the difficulty of diagnosing fœtal syphilis from an examination of the placenta. Indeed, on one occasion, when asked to obtain a syphilitic placenta, he had had the greatest difficulty in finding one. He considered, however, that examination of the umbilical cord was most important, even if the Wassermann reaction was negative. Spirochætes are demonstrable in the arterial walls, as well as endarteritis. From the examination of 100 cases of stillborn fœtuses, he believed that syphilis is a very rare cause of antenatal death.

Dr. WALTER SWAYNE, from an investigation of the Wassermann reaction in the case of new-born infants, was of opinion that syphilis is much less common as a cause of infant death than is suspected. Certainly a positive Wassermann reaction is much more difficult to obtain in new-born infants, even if obviously syphilitic, than in adults.

Extra-Uterine Pregnancy.

Dr. GORDON LUKER (London) read a Short Review of Cases of Extra-uterine Pregnancy admitted to the Gynæcological Department of the London Hospital during the Years 1913 to 1920. 253 cases of extra-uterine gestation were admitted to the hospital during the period in question. The age of the patients varied from 18 to 52, the latter being a case of secondary abdominal pregnancy with death of the fœtus some years previously. Operation was performed in 240 cases. Acute rupture of the tube was noted in 68 cases; tubal mole was found in 51 cases; tubal abortion occurred in 29 cases. Of the 240 operations, 37, or 15 per cent., were special emergency operations, in which the condition of the patient demanded immediate interference. Six deaths occurred, 3 from shock and hæmorrhage, 1 from pulmonary embolus, 1 from broncho-pneumonia, and 1 from peritonitis. Of the former, 1 death occurred in a patient who was not operated upon; 2 deaths from shock and collapse occurred within 12 hours of operation, and raised the question whether it is advisable to delay operation in some cases where shock is profound. Of rare conditions, 3 cases of pregnancy in a rudimentary horn were noted. In a more detailed examination of 42 cases admitted in the year 1920 it was found that in 30 per cent. no previous pregnancy had occurred. Some considerable period of sterility had generally elapsed since the last confinement. There were 2 cases of repeated tubal pregnancy, and inflammation in the pelvis or other tube was definitely noted in 11 cases. As to the symptomatology, Dr. Luker found that in 28 cases—i.e., 66 per cent.—the ordinary history of amenorrhœa was obtained. In 10 cases a period had not been missed—that is to say, bleeding occurred at or within a month from the last menstrual period. In 4 cases no bleeding at all occurred up to the time of operation. In one of these cases the abdomen was full of blood which had come from a ruptured Graafian follicle, and no evidence of pregnancy in the tube or ovary could be found. Where no bleeding from the uterus occurs it is probable, therefore, that either an atypical condition is present or that the ovum is still living. In nearly half the cases acute pain occurred as the first symptom. In several a dull "girdle" pain was complained of, and was found to be of some value in assisting diagnosis. The passage of a decidual cast of the uterus is pathognomonic of tubal gestation, and when carefully looked for can be found in nearly half the cases. It is shed more often after than before operation. The differential diagnosis from salpingitis, a small ovarian cyst, and appendicitis is often difficult, the pulse-rate being the most useful guide. Any considerable rise of temperature points to an inflammatory condition rather than to extra-uterine gestation.

Dr. **LAPTHORN SMITH** (London) referred to several cases where diagnosis had been difficult, and urged the importance of early operation when diagnosis was in doubt.

Dr. **C. E. PURSLOW** (Birmingham) thanked Dr. Luker for his valuable record of an unusual number of cases very concisely put. He referred to rectal tenesmus as being an important symptom, although occasionally diagnosis may be very difficult. For example, he had met with cases of typical uterine abortion associated with a tubal mole.

Dr. **EARDLEY HOLLAND** referred to the difficulty of diagnosis, inasmuch as the typical signs of amenorrhœa, hæmorrhage, and pain are not always present. With regard to the causation of tubal gestation, lately he had been examining the opposite tube for signs of inflammation, and had found it in three-quarters of the cases investigated.

Dr. **A. E. GILES** referred to the two schools of thought that exist with regard to the causation of tubal gestation. The one believes that the tube is normal, and the other that it is diseased in all cases.

Dr. **HERBERT WILLIAMSON** drew attention to the difficulty in diagnosis between ectopic gestation and theca-lutein hæmatoma. In the latter the menstrual period is often late, there is acute abdominal pain, followed by hæmorrhage, and the picture is thus typical of tubal gestation.

Dr. **CARLTON OLDFIELD** also referred to the point of diagnosis raised by Dr. Williamson, which he considered very important. Repeated attacks of pain are more suggestive of hæmatoma than tubal gestation.

Dr. **W. S. A. GRIFFITH** thought that the breast changes might prove useful in the diagnosis between these two conditions.

Dr. **HERBERT WILLIAMSON** pointed out that breast changes also occur in the case of lutein cysts due to the stimulating action of lutein.

Dr. **WALTER SWAYNE** showed a specimen of a malignant neoplasm involving the small intestine, which he had removed from a nullipara, and which had been reported to be chorion-epithelioma by the pathologist to whom the specimen had been submitted.

Dr. **T. G. STEVENS** said that if the diagnosis was accepted it was a most important specimen. Personally he believed that it was a carcinoma, and in the section that he had examined no syncytium was present. The only thing suggestive of chorion-epithelioma was the large amount of hæmorrhage into the tissues. The specimen was referred to the Pathological Committee of the Royal Society of Medicine, Obstetrical and Gynæcological Section.

Prof. **HENRY BRIGGS** exhibited specimens and illustrations showing the pathology of various uterine polypi.

This concluded the business of the Afternoon Session. A dinner was held at the Queen's Hotel at 7.30 P.M., at which over 60 members of the Congress were present.

On June 4th, at 10 A.M., gynæcological operations were performed at the General Hospital, Birmingham, by Mr. Beckwith Whitehouse, and at the Women's Hospital by Dr. F. Edge and Mr. J. T. Hewetson. At the Queen's Hospital, by invitation of Dr. Purslow, Prof. Fothergill demonstrated his operation for the cure of genital prolapse.

Golf and excursions to places of interest were arranged for the afternoon.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

EXHIBITION OF CLINICAL CASES AND SPECIMENS.

A CLINICAL meeting of this Section was held on June 10th, Mr. W. T. **HOLMES SPICER** occupying the chair.

Speculum to Prevent Pressure on Globe.

Dr. **R. WALLACE HENRY** showed a speculum which he had designed and used for the purpose of preventing a patient pressing his eyelids together and thus exerting pressure on the globe after an opening for any purpose had been made. He had used it with decided advantage after many cataract extractions, and since employing it he had lost no vitreous in any case. His custom was to leave the speculum in position until the extraction of the lens and the toilet was completed. The device was favourably received.

A Desk for Myopes.

Dr. **F. H. MOXON** exhibited a desk which he had designed for the use of children who were predisposed to myopia. He had found that children who at school persistently applied the eyes close to the paper being written on or the book being read, later developed myopia, even though examination showed them to have only slight hypermetropia or hypermetropic astigmatism. This apparatus keeps the eyes at a certain distance from the book by means of a glass screen. The use of it successfully broke the habit of close application of the eyes after a short time.

Acute Macular Disease.

Dr. **RAYNER D. BATTEN** read a note on two cases which he showed of acute macular disease. He said that cases frequently occurred in which changes in the macula were the only evidence of disease and failure of sight unassociated with other forms of retinitis. There was a great discrepancy between the physical signs, as shown by the ophthalmoscope, and the symptoms. When a really good light was available, fine pigment changes which now escaped observation would be visible; these were better seen by looking to one side of the macula than by looking straight at it. The two acute cases he now showed were not unlike those in the familial amaurotic idiocy in regard to the fundus changes. Causes at work in the cases he had so far seen had included pyorrhœa, suppuration of nasal sinuses, gonorrhœa, influenza and other illnesses, and pregnancy.

Fundus Changes in Three Brothers.

Mr. **W. H. McMULLEN** showed three brothers with fundus changes of differing character, but with one feature in common—viz., the development of abnormal connective tissue, either on the surface of the retina or the vitreous. There were several possibilities: (1) that the changes were of inflammatory origin; (2) that they were degenerative in nature; (3) that they resulted from intra-ocular hæmorrhage; (4) that they were due to developmental defects. He regarded them as cases of atypical retinitis proliferans. The brothers were members of a family of 13 children (9 boys, 4 girls). Three of the boys died between the ages of 2½ and 5 years, and of the six surviving boys, four had defective sight. No female in the family had bad sight. Three great grand-aunts died blind.

Mr. **G. WINFIELD ROLL** exhibited a patient showing macular changes. There could be seen plaque of what appeared to be organised fibrous tissue in each eye. There was complaint of failure of sight during seven years, which had become worse in the last two years. The field for white and red was practically normal, but the patient scarcely perceived yellow or green at all. In one eye there appeared to be a hole in the fibrous tissue.

Other cases shown included one, by Miss **MANN**, of an atrophic condition of the iris; of an unusually large cyst of Moll's gland by Mr. M. S. **MAYOU**; and by Dr. R. L. **REA**, a case of retinal disease of doubtful character.

A New Surgical Lamp.

A new lamp, called the "Scialytic" lamp was on view, and was demonstrated on behalf of the makers. It has been specially designed for surgical and laboratory work.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

AT a recent meeting of this Society Mr. **TIFFENEAU** read a paper on

Hyoscyamine and Atropine

in which he stated that hyoscyamine, the principal alkaloid in belladonna, was twice as active as atropine, which was a racemic alkaloid composed of equal parts of lævorotatory and dextrorotatory hyoscyamine. While the two alkaloids, atropine and hyoscyamine, presented considerable differences as regards their peripheral effects, they appeared to be equally active in their toxic action on the central nervous system, as Cushny had shown. From an economical standpoint the substitution of hyoscyamine for atropine would be of great advantage, as it would render laborious manipulations unnecessary and save twice as much of a product which had to be imported from abroad (Egypt and India).

The Use of Lysidine in Chronic Rheumatism.

MM. **BITH** and **BOURNIGAULT** stated that bitartrate of lysidine, which had been used as a remedy for gout and rheumatism in Germany from 1892–9 by Ortowski, Mendelssohn, Wolf, and Grawitz, was a white, tasteless, inodorous powder, very soluble in water and of only slight toxicity. Clinically it appeared to diminish the pain in chronic rheumatism and to improve the functional movements without having any action on the deformities. Chemically it had an action on the general nutrition characterised by a rise in the nitrogen coefficient from 82 to 85 per cent. in man and from 85 to 89 per cent. in woman. It had no effect on the elimination of phosphorus. It had considerable influence on the elimination of chlorides, which increased from 11·70 g. to 14·70 g. and 13·50 g. in man and from 8·96 g. to 12·16 g. and 12 g. in woman. It had an important effect on the elimination of purin bodies, especially uric acid, and to a less extent of the purin bases. In the blood there was a diminution of the total nitrogen, especially the residual nitrogen. The drug did not appear to have any bad effect on the kidneys, for albuminuria present before the treatment did not increase.

Decalcification and the Need of Calcium in Tuberculosis.

MM. **RENÉ LAUFER** and L. **LEMATTE**, after alluding to Mr. Laufer's recent communication on this subject,[1] stated that in practice 1·75 g. to 2 g. of calcium were sufficient for the needs of the tuberculous subject, and that the other minerals, such as magnesium, sulphur, potassium, iron, silicon, &c., were equally indispensable.

MM. **GASTON-DURAND** and S. **NEMOURS-AUGUSTE** read a paper on

The Action of Diathermy on the Post-operative Sequelæ of Appendicitis

in which they stated that bipolar application of a strong high-frequency current had a good effect on the pain and digestive disturbances caused by chronic epiploitis which fairly frequently persisted after an operation for chronic appendicitis. The method was specially suitable for cases in which clinical and radioscopic examination showed no evidence of perityphlitis or pericolitis, or as a palliative method when the patient refused another operation.

The Use of Enemata of Ox-bile for Constipation.

Mr. G. **LEMOINE**, of Lille, stated that he had obtained the best results in the treatment of constipation in adults by an enema of 200 g. of boiled water containing two or three tablespoonfuls of glycerinated ox-bile. In infants of or 3 months and upwards he had obtained equally good ts by using a ball syringe containing a teaspoonful of inated ox-bile mixed with water.

Reviews and Notices of Books.

MEDICAL THERAPEUTICS OF THE EAR, NOSE, AND THROAT.

Précis de Thérapeutique Médicale Oto-Rhino-Laryngologique. Par G. DE PARREL, Ancien Chef de Clinique à l'Institution Nationale des Sourds-Muets de Paris. Paris: A. Maloine et Fils. 1921. Pp. 670. Fr.28.

THIS is a colossal treatise on the medical treatment of disease of the throat, nose, and ear, wherein all descriptions of operations are omitted, except for some minor surgical procedures. Moreover, no attempt is made even at a thorough discussion of the indications for operation. This limitation of scope naturally diminishes the value of a work on the therapeutics of regions where the treatment is now so largely surgical, but we obtain a large amount of sound advice and a number of useful prescriptions.

The first part of the book, on "General Considerations and Pharmacology," is a kind of catalogue of the drugs in common use. The second, and longest, part is devoted to the treatment, respectively, of diseases of the ear, nose, pharynx and larynx, beginning in each case with an account of the various methods of applying medicaments to these regions, and of minor manipulations. The treatment is, on the whole, in accord with English practice, but, as is usual in French literature the only treatment of hypertrophied tonsils described is "morcellement" under local anæsthesia. A section on vaccine therapy by Dr. Michel Copendy contains a generous appreciation of the work of British investigators; the writer insists on the greater efficacy of sensitised vaccines and claims surprising results in the treatment of such diseases as middle-ear suppuration and nasal sinus disease. A detailed discussion of voice-training and the treatment of vocal defects is followed by an account of the teaching of lip-reading, which the author is well fitted to describe by reason of his connexion with the Deaf and Dumb Institution of Paris. But between these sections is a long chapter on re-education of the deaf which will, we fear, fail to convince the sceptical of the value of this form of treatment. The section on electrotherapy is disappointing and, after a short account of treatment by X rays and radium, is followed by a long chapter on balneotherapy, which is very popular in France. This chapter is perhaps the most interesting of all to the English reader, and should be a useful guide to those wishing to send patients with throat affections to the French spas.

The book, as a whole, suffers from being too long, and too voluminous; the more strictly surgical affections, such as tumours, might with advantage have been entirely omitted.

HYGIENE AND PUBLIC HEALTH.

Manual of Public Health. Fourth edition. By W. G. AITCHISON ROBERTSON, M.D. London: A. and C. Black, Ltd. 1921. With 25 illustrations. Pp. 260. 10s. 6d.

PREVIOUS editions of this book contained accounts of medical jurisprudence, toxicology, and public health combined in one volume. The present edition is issued in two parts, one dealing with medical jurisprudence and toxicology and the other with public health, and it is with this latter volume that we are at present concerned. Presumably, Dr. Robertson had in mind, when writing the book, the needs rather of the student of medicine than of the candidate for the diploma in public health, since the work appears to be well suited for the former purpose, but is not sufficiently comprehensive for the latter. He has presented in a readable form a brief survey of the more important features of hygiene and public health. We are, however, unable to endorse certain of his statements. In discussing the theory of aerial convection of small-pox, for example, he says :—

> "Many affirm that the infection is also carried through the air for considerable distances, basing their assertion on the fact that infection has spread in many cases for a distance of fully half a mile around small-pox hospitals. In many of these cases, however, the influence of personal intercourse has had much more to do with the spread of the disease than aerial convection, and in many hospitals laxity regarding isolation has been great."

It would be interesting to know on what data the author bases this assertion. It is true that the aerial convection theory has not received universal credence, but, in the present state of our knowledge, it is not possible to prove that it does not take place, and it is the hypothesis which best fits the facts recorded by some of our ablest epidemiologists.

The section on sanitary law is, in our view, unsatisfactory. No distinction is made between the laws regulating sanitary matters in England and Wales, Ireland, or Scotland. A subject like the law does not admit of such haphazard treatment. On the whole, however, medical students will find this manual serviceable and clear.

Hygiene. Ninth edition. By J. LANE NOTTER and R. H. FIRTH. London: Longmans, Green and Co. 1921. With numerous illustrations. Pp. 510. 10*s.* 6*d.*

IN the ninth edition of this elementary book on hygiene, by the authors of a standard text-book on the subject, little change has been made in the general plan. It has, however, been found necessary to revise or rewrite certain parts in order to bring them up to date. Thus, the sections dealing with the theory of dietaries, the treatment of sewage, and the infectious diseases have been modified, while, owing to recent legislation, that on sanitary law has had to be amplified. A short section on the sanitation of camps has been added, and a new chapter on child welfare and school hygiene introduced. These modifications and additions enhance the value of an excellent treatise. The authors have compressed a vast amount of useful and interesting information into a relatively small space, and the book can be confidently recommended to the student of hygiene and public health.

Barrier Charts for Health Officers. By S. H. DAUKES, M.B., D.P.H., &c. London: Baillière, Tindall and Cox (for the Wellcome Bureau of Scientific Research). 1921. With 4 folded Charts. 3*s.* 6*d.*

Dr. Daukes has produced in the form of four tabular cards a concise synopsis of preventive measures against communicable diseases. The different forms of barrier which a knowledge of sanitation enables us to interpose between the sick and the healthy are conveniently shown in columns printed in different coloured ink from that used for the rest of the chart. The charts, in a less complete form, have had an extensive trial at the School of Army Sanitation in Leeds, and we have no doubt that in their revised and extended form they will be distinctly useful for teaching purposes. Public health officers will find them convenient for reference purposes in emergency outbreaks. Perhaps the charts will be most appreciated by members of the Navy, Army, and Indian Medical Services, whose regular lot it is to deal with communicable diseases in tropical climates. The usefulness of the charts is increased by the introduction of information as regards incubation, period of infectivity, and quarantine.

THE CHILD'S PATH TO FREEDOM.

By NORMAN MAC MUNN, B.A. Oxon. London G. Bell and Sons. 1921. Pp. 163. 2*s.* 6*d.*

THE idea of absolute freedom for the child, in order that he may work out his own salvation, is no new doctrine in these days, but its exponents are even now few in number compared with orthodox teachers, and are possibly still more disproportionately inarticulate. Mr. MacMunn published in 1914 a volume called "A Path to Freedom in the School," and this has now been revised and largely rewritten under a slightly different title. The book is an able and luminous statement of the position taken by the educational reformers, and being written with real psychological insight and skill, backed by practical experience, carries much conviction to the mind of the unbiased reader. The book is designed to show that the present system of "class-teaching by adults" is incompatible with the modern view of the intuitively purposive nature of a child's play, but its teaching is really much more constructive than this. Mr. MacMunn points out that "there is no analogy whatever between the effects of partial and of complete freedom," and while many even of the more advanced teachers would hesitate to go the whole way with him, nothing short of this would give his system a fair trial. It is at any rate certain that schools run on the lines pictured by Mr. Mac Munn would produce boys and girls of an entirely different stamp from the product of ordinary schools.

Theories as to discipline, ways of teaching and of learning, and cognate subjects are expounded in detail, criticisms and objections being squarely faced. Mr. Mac Munn pleads for a revolutionary change in our educational policy, and since his suggestions are not unpractical, the book is one that no serious student of education can afford to ignore.

THE YEASTS.

By ALEXANDRE GUILLIERMOND, D.Sc. Translated, in collaboration with the Author, by F. W. FARMER, Ph.D. London: Chapman and Hall.; New York: John Wiley and Sons. 1920. Pp. 424. 33*s.*

IT will be generally agreed that no class of micro-organism has been more intimately associated with the progress and development of the human race than the yeasts. Microscopic examinations have revealed the presence of yeast cells in bread found with Egyptian mummies, and from the earliest times of which there is any record beverages fermented with yeast were consumed. To-day the yeasts are of increasing interest and they are assuming greater importance in medicine, especially in relation to certain deficiency diseases. From the technical standpoint the compressed yeast industry in this country and America is singularly well organised both as regards manufacture and distribution. The literature on yeast is to be found scattered in a number of scientific and technical journals and in treatises dealing with certain industries, but so far as we are aware Dr. Guilliermond is the first author to collect the various data relative to yeasts in one volume and to arrange it in a manner available to biologists, practitioners in industrial work, agriculturists, and physicians. The subject-matter of his book is dealt with under the following heads: Morphology and development of the yeasts; Cytology of yeast; Physiology, Nutrition, Respiration, and Alcoholic fermentation; Origin of the yeasts; Methods of culture isolation, characterisation, and identification of yeasts; Variation of yeasts; Classification of yeasts; Fungi related to the yeasts.

While this edition is claimed to be more than a translation of the author's original "Les Levures" published in 1912, certain of the chapters enumerated are disappointing. The information is not always up to date, and there is no critical summary of our present knowledge of some of the subjects discussed. The wording is often careless and not always lucid. and there are also a number of errors, particularly in the spelling of authors' names; moreover, the chemistry is sometimes shaky—for example, hydrocarbon is used where carbohydrates are intended. In spite of these annoying blemishes the book is a really useful one; it is well illustrated and printed, and there is a good bibliographical index.

JOURNALS.

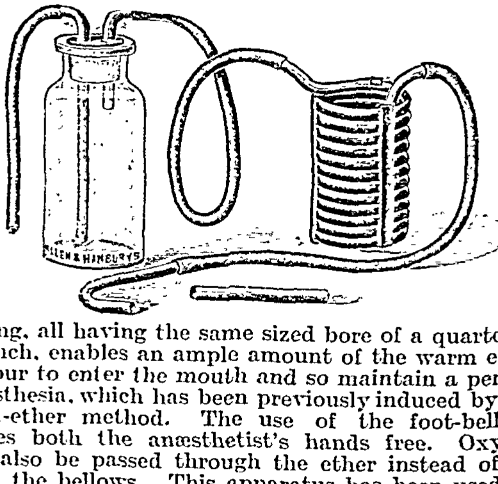
Journal of Laryngology and Otology. May and June, 1921. Vol. XXXVI., Nos. 5 and 6.—In the May number Miss Gladys Boyd reports on 188 consecutive cases of the Schwartze operation from the Edinburgh Royal Infirmary. Three further cases were found at operation to be furunculosis. Of the 188 cases, 112 were patients under 21 years of age; 6 cases arose after operations on the nose or pharynx; conservative treatment, including paracentesis, had been tried and had failed in 17 cases; in 8 cases death resulted, and was due to intracranial complication. The paper contains numerous interesting details. There is an abstruse article by Prof. R. Bárány, of Upsala, on the diagnosis of disease of the otolith apparatus; Mr. Herbert Tilley reports three cases in which diphtheria carriers were cured by enucleation of the tonsils, and Dr. Logan Turner describes two cases of successful operation on adhesion of the soft palate to the pharynx by Tilley's method of fixing temporary ligatures from the separated palate to the incisor teeth.——The June number opens with a sane but discursive article on some discarded theories and methods by Dr. P. McBride, which is followed by two papers on injuries to the ear in warfare by Mr. Jefferson Faulder and Mr. Lionel Colledge. Finally, Dr. Dan McKenzie reviews an undulatory theory of olfaction put forward by M. A. Heyninx. The reports of societies' proceedings are still more than a year behind.

In the *Journal of the Royal Army Medical Corps* for June, Lieut.-Colonel W. F. Tyndale, C.M.G., discusses medical staff work of an army in war-time, showing the great responsibilites of a Director of Medical Services and his staff, which must be small but very hard-working. "Keep the officer staff small, work the officers hard, but get them their leave regularly." The A.D.M.S. of his division worked regularly 9½ hours daily for seven days a week. His advice on choosing officers for the staff will be carefully read and remembered by all junior officers who can profit by them. He prefers officers with higher qualifications. "Of all the tests of the good and bad points in an officer give me a hasty retreat as the best," shows how different are the problems of a civil practitioner and an army medical officer.—Captain William Wallace, writing on the vision of the soldier, notes that in the pre-war British Army the standard of vision was high and invariable, and that "the amazing shooting of the original Expeditionary Force, and the endurance of that heroic first (and only) line are triumphant testimony to the soundness of the War Office policy of selection, organisation, and training." He tells how the standards of vision were altered in the war, observing that, before the war, the examiner had to take care that no man with poor vision slipped into the army, but with the coming of conscription the difficulty was to ensure that a man did not succeed in simulating defective sight, and so unfairly escape service. On the other hand, when visual standards are lowered, men may join the service with serious ocular defects and consequent unjustifiable claims to pension which will be hard to resist. This paper should be read by all members of medical pension boards and inspectors of recruits.—Miss Margaret W. Jepps reports the treatment of amœbic dysentery cases in the University War Hospital, Southampton, during 1918–19. The recommended treatment is—At night: chlorodyne, ♏10; half an hour later emetine bismuthous iodide, 3 gr. in emulsion in liquid paraffin. ʒss., repeated nightly for 12 days. Of 63 cases so treated, only 13 per cent. relapsed. When this failed, emetine hydrochloride, 1 gr. hypodermically daily for 12 days, cured three out of five patients treated.—Major N. V. Lothian and Captain A. R. l, of the Royal Army Medical School of Hygiene, kpool, give a detailed account of the "Activated " method of sewage disposal proposed by Mr. rth of Sheffield. They consider it worthy of ead adoption, being effective, and economical allation and maintenance. Sewage sludge when it has "ripened," contains rotifera and infusoria, which establish themselves at the expense of pathogenic micro-organisms; there are also nitrifying bacteria. Mixed with fresh sewage in proper proportions and kept stirred up by paddles, in eight hours the aerated sludge secures a purifying effect that is all that is wanted. The effluent is fit for discharge; total organisms are very greatly reduced; there is entire absence of nuisance; and no chance is given for flies to breed.—Major L. Avery, D.S.O., R.A.M.C., T.F., proposes changes that seem needed from the point of view of a medical officer who served with mounted troops in the nearer East throughout the war. He would like to see the regimental stretcher-bearers drawn not from the regiment but from the trained R.A.M.C. personnel of field ambulances increased in establishment accordingly; he proposes a lighter stretcher, in two parts so that it may be packed on a pack-saddle, and a better medical cart, and asks that all needles of syringes shall have standardised nozzles, whether for 10 c.cm. or 1 c.cm. syringes.—Captain J. S. K. Boyd, with others, has tried to find benefit from vaccine therapy in acute gonorrhœa, but whether he gave in four weeks 600 millions or 2450 millions of gonococci he could see no clinical advantage, and indeed the cases that got vaccine remained longer in hospital and did not suffer less from complications. Under current literature is a quotation from the Scandinavian *Arch. f. Physiol.*, in which Töttermann states that in roughly alternate weeks of teetotalism and moderate drinking he could thread more needles in 20 minutes during the teetotal periods. Fatigue seems to have come on in those weeks less quickly.

New Inventions.

OPEN-ETHER ANÆSTHESIA DURING THROAT OPERATIONS.

THIS is an apparatus for maintaining anæsthesia by the administration of open ether during operations on the throat. As will be seen by the illustration, it consists of a Woulff's bottle and a coil of malleable metal (12 circles, each 9 inches in circumference), which is placed in a vessel containing hot water, whereby ether vapour becomes heated. A foot-bellows is used for sending air through the ether contained in the apparatus. The warmed ether vapour continues through the rubber tubing to a flexible metal tube, 6 inches long, which is placed in the mouth and is easily adjusted to the required position by its flexibility. The rubber and metal tubing, all having the same sized bore of a quarter of an inch, enables an ample amount of the warm ether vapour to enter the mouth and so maintain a perfect anæsthesia, which has been previously induced by the open-ether method. The use of the foot-bellows leaves both the anæsthetist's hands free. Oxygen can also be passed through the ether instead of air from the bellows. This apparatus has been used by me for the operation of enucleation of tonsils by dissection in a vast number of cases during the last 2½ years. The makers are Messrs. Allen and Hanburys, Wigmore-street, London, W.



HAROLD SINGTON, M.D. Brux., M.R.C.S.,
Senior Anæsthetist, Hospital for Sick Children, Gt. Ormond-st.

THE LANCET.

LONDON: SATURDAY, JULY 2, 1921.

The X Rays in Malignant Disease.

DURING the past week there have been articles in the lay press inspired from the West London Hospital and based upon a striking demonstration of a new method of using the X rays for the treatment of malignant disease. We may remind our readers that a description of some of the most important details of this, the Erlangen, method were given in THE LANCET of Jan. 1st last, in a report of the proceedings of the Section of Electro-therapeutics of the Royal Society of Medicine. Since that time medical men have been investigating the method as far as circumstances have permitted. As in all similar methods of treatment, the basic principle involved is that radiations of the gamma type—whether from radium or an X ray tube—have at first a stimulating and, as the dose is increased, a destructive effect upon living cells; and it is found that cells of the embryonic type are more susceptible to these rays than normal tissue elements. It thus follows that a malignant cell invading normal structures may be destroyed without serious damage to the latter. It is necessary to keep these facts in mind while testing the claims put forward from Erlangen, a place very favourably situated for the elaboration of X ray technique. The method in its present form is the outcome of an enormous amount of work patiently carried on for years under skilful guidance.

Briefly stated, the position now is that a highly efficient type of radiation has been attained, one that can be standardised within narrow limits and reproduced at will for as long as is required for practical purposes. The necessary dose to destroy a malignant cell has been ascertained, and a way evolved for giving this dose to any required depth; and it has been proved beyond doubt that if every part of a localised malignant growth receives this dose, that growth will almost certainly disappear. If it does not do so the reason is most likely to be faulty technique; it may be due to extension of mischief beyond the apparent field of involvement, or because the health of the patient is without recuperative power. This last point is one that does not always receive the consideration it demands. As a matter of fact, it is useless to expect any appreciable degree of success in patients whose health is more or less seriously impaired, and whose blood count is not approximately normal. Efficient irradiation produces marked blood changes, notably a sharp fall in the red corpuscles, requiring from six to eight weeks of generous feeding to restore, and until this is accomplished it is inadvisable to give the second or third irradiations required in certain cases. All these facts have been arrived at after minute investigation based on thousands of applications, where careful records have been made of the effects produced. The records are in keeping with theoretical considerations, supporting belief in their substantial accuracy. There is another point to be remembered: it has been found that if a carcinoma cell receives a dose of X rays rather less than half the full cancer dose the effect is one of powerful stimulation, resulting in appreciable increase in size of the growth, with possibly fatal results. This is one reason why the full dose is given at one sitting.

We may now consider the routine adopted at the Frauenklinik in Erlangen for all cases of malignant disease. Immediately the nature of the case is clear the patient is sent to the X ray department for appropriate treatment, primary surgical operation being definitely abandoned, save in the single case of primary carcinoma of the ovary, where the tumour is at least as large as a hen's egg. Here the mass of the tumour makes full irradiation of the area difficult, and it has been found best to remove it and irradiate more or less immediately afterwards. Cases of uterine carcinoma treated by this method have shown over 80 per cent. "clinically cured" after 3½ years, and the results in other regions are reported as equally favourable. Among medical men in this country such statements are received with doubt, but while such caution is commendable, we would venture to remind our readers that we are here concerned with a technique which is radically different from anything usually practised in this country, and that with our less perfect methods radiologists have never had a chance to show the possibilities of the X rays in the treatment of cancer. Surgical operation is the accepted routine, and the X rays are not used until afterwards, either as a prophylactic or when recurrence and extension have made further operation inadvisable. This practice has been the correct one in the light of our knowledge and experience, and no praise could be too extravagant for the skill and patience of our surgeons in their efforts to deal with appallingly difficult problems. If many cases of malignant disease can be shown to do better under radiological than surgical methods, not a few surgeons will hand them over to the radiologist with a feeling of intense relief. In spite of all the work and skill expended the results of the treatment of malignant disease by operation are not brilliant, and it looks as if superior results are being attained by the methods elaborated by Professor WINTZ at Erlangen. If comparable results are to be aimed at in our clinics, the cases must go to the radiologist before any operation is done. After long and careful observation it is the considered opinion of the gynæcologists at Erlangen that surgical operation definitely increases the danger of metastasis.

It will be seen that the suggestions in the lay press, that cases of malignant disease should go to the radiologist immediately the diagnosis is made and before operation, are based on the practical experience of competent observers. There is little doubt that the time has come for us to reconsider our position in dealing with the situation. Assuming the claims for the irradiation of malignant cases to be substantiated, the advantages to be gained will be readily appreciated. Apart from the higher percentage of apparent cures, cases would come under observation at an earlier stage; the dread of the major operation causes many to hide their trouble until the chance of more or less permanent relief has definitely passed.

The Bacteriology of the Alimentary Canal.

IN two years' time pious microscopists will commemorate the bicentenary of the death of ANTHONY VAN LEEUWENHOEK, whose portrait has been adopted by the American bacteriologists as their sigillum. That great and good Dutchman is commonly supposed to have been the first to perceive clearly the forms and shapes of bacteria, to appreciate that they were alive, and to imagine that they were of importance. Claims of priority are always upset sooner or later by diligent students of the past, for discovery is a process and not an event, but whether Leeuwenhoek really did make the first microscopes through which bacteria could be plainly seen or not, he will always be remembered for having pointed out so clearly the abundance of microscopic life in the mouth. Like Stephen Hales and the other great pioneers, he recognised also the necessity of quantitative information, and hazarded the approximation that there were as many bacteria in one hollow tooth as there were men in Holland. The mouth, indeed, contains an embarrassing assemblage of micro-organisms, many of them in enormous numbers. Certain streptococci, for example, are so numerous that they have been used by M. H. Gordon in his ingenious researches as a test for the range of the droplets of saliva ejected by our representatives in the House of Commons during their orations. More than a hundred different varieties of bacteria have been found in the mouth, and it is still very uncertain what most of them do. Some are certainly capable of pathogenic activity; the pneumococcus is often present, and the demonstration by Pasteur and Sternberg that mice could be killed by the injection of normal saliva is one of the landmarks in the history of bacteriology. Streptococci get into decayed teeth and cause root abscesses, from which they may spread to the joints or heart valves. Whether any of the spirochætes or amœbæ or the *Bacillus fusiformis* are primarily pathogenic is not altogether clear; they are much more abundant in and about various inflammatory affections than under normal conditions, but it is at present impossible to be sure which is cause and which is effect. Perhaps pyorrhœa is like grouse disease, which, with no specific cause, is the cumulative result of an abnormal excess of a variety of parasites working in an alimentary canal depressed by bad hygienic conditions.

Such of the mouth flora as is carried on with the food disappears in the stomach. Under normal conditions the acidity of the gastric juice definitely stops multiplication, and seems actually to kill the great majority. In dilated and other diseased stomachs there is pretty free growth, but here again the flora of yeasts, Boas-Oppler bacilli, and so on, is a special one, and not a diluted replica of that in the mouth. The duodenum is normally sterile, except when food is passing along, and even then there are quite few organisms. As scrutiny goes further down the bowel the organisms progressively increase, so that in the ileum there are many streptococci and *B. coli*, the relative proportions of the two depending rather on the nature of the food; worms, too, produce a striking local increase of bacteria, which in the upper part of the small bowel are mostly or entirely streptococci. In the large intestine, with its greater lumen, relatively stagnant contents, and alkaline reaction, yet another habitat is found with its own special flora. *B. coli* in its different kinds becomes enormously abundant, and various streptococci, spirochætes, and sometimes amœbæ flourish. Here, too, is the great breeding-ground of the sporing anaerobes; the technical difficulties of their cultivation and separation shielded them from the prying curiosity of bacteriologists pretty thoroughly until it was realised that they included some which, like *welchii*, might on occasion be of the most urgent genic importance. The residue of this vast rial population constitutes about a quarter of weight of normal fæces. It is reckoned, by methods more precise than those of Leeuwenhoek, that an average motion contains many more bacteria than there are men, women, and children in the whole world. Most of them are dead; those still living are principally *B. coli.*

We have, then, in the alimentary canal a series of areas which differ in their physical and chemical circumstances, and in their inhabitants in the same sort of way as a beech wood on chalk differs from an oak wood on clay. Differences in the amount of available oxygen, in the host's food as it is digested and absorbed, in the secretions and excretions of the intestine, in the activities of the bacteria themselves, all contribute to produce a series of habitats, each with its characteristic flora; their study is evidently part of what botanists call œcology. What is of particular interest in the present case is that the different floras have all been demonstrably sorted out from the same original material coming in through the mouth; their establishment is effected in a few months. It follows, too, that the examination of the bacteria of the fæces tells us, more or less, what organisms there are in the stools, and nothing else; if we want to know what is going on in the small intestine we might as well investigate the mouth. Of the utility of these organisms we know even less. Looked at from our own point of view, it is certain that life of at least a tolerably normal sort is possible without them, though this, of course, affords very slight grounds for an opinion that we derive no benefit from them under ordinary conditions. They definitely enable ruminants to get energy out of cellulose, they may synthesise vitamins, and their products, no doubt, help a bowel to act naturally when it has grown up to be accustomed to them. Contrariwise, it is by no means certain that sterility of the intestine would abolish the many ills, from hypertension onwards, that have been all too glibly assigned to the activities of the organisms there. We have to look at the matter from the point of view of the organisms, for whom the alimentary canal provides a series of congenial homes in which they can achieve ideals which are not proved to be entirely mischievous in design.

◆

Operative Treatment of Prolapse of the Uterus.

Prolapse of the uterus is undoubtedly the cause of a great deal of discomfort to many women, and of profound suffering to women of the working classes, and the treatment of this condition and the performance of operations for its relief take up a large amount of the time of the practising gynæcologist. A great deal has been written upon its exact cause and there is even yet a good deal of disagreement as to the precise nature of the supports of the uterus and the particular rôle they respectively play in maintaining this organ at its normal level. It is becoming more and more common to practise some form of operative cure for the condition, and the radical cure of a prolapse is nowadays as common an operation as the radical cure of a hernia. It is natural, therefore, that a large number of operations differing but little in detail should have been devised for this condition. But their number and complexity prove that the results are not always such as might be desired. The radical cure of a case of "falling of the womb" is not a difficult attainment, no matter what operation is performed, in a woman past the child-bearing period of life; but a procedure which will stand the test of subsequent child-birth is much more difficult to devise. The problem is complicated by the ready distensibility of the vagina and pelvic floor and the extreme degree of stretching which these structures have to undergo during the passage of a fœtus. For these reasons many operators in the past attempted, as some even at the present time attempt, to reinforce the plastic procedures carried out on the vagina by some method of fixation of the uterus, so as to overcome the wedge-like action of that organ and its tendency to stretch again and to descend through the vaginal passage. Any operation, however, which fixes the uterus contravenes the normal anatomy and physiology of the part, and converts what should be a readily mobile organ into a fixed one. Further than this, whether the fixation be carried out by the vagina or by the abdomen, it complicates and increases the immediate and remote dangers of the operation. For these reasons many gynæcologists content themselves with operations performed by the vaginal route alone and do not advocate any method of fixing the uterus, whether by the vagina or the abdomen.

At the recent British Congress of Obstetrics and Gynæcology held at Birmingham this matter was very fully discussed, when papers were read by a number of gynæcologists advocating vaginal operations only, reasoning that, as these procedures gave permanent results which did not prevent pregnancy and would stand the test of parturition, abdominal interference was unnecessary and therefore undesirable. Most of the speakers who took part in the discussion endorsed this view of the matter. It has been objected to the operation of ventrofixation, when employed as a means of supporting the uterus in cases of prolapse, that it not only increases the risk of the operation by necessitating the opening of the abdomen, but that it may give rise to serious interference with the course of parturition in the event of pregnancy ensuing, and that it leads to a very considerable risk of subsequent intestinal obstruction when practised in the ordinary manner. No doubt this is true of at any rate some of the methods of carrying out this procedure. It is, however, possible, as the paper published in THE LANCET of June 18th by Dr. J. E. GEMMELL and Mr. A. L. ROBINSON shows, to carry out this operation in such a manner as to cause no undue risk, to entail no interference with subsequent pregnancy and labour and, in a large majority of the cases, permanently to cure the patients of the symptoms for which the operation is undertaken. They practise a procedure in which the utero-vesical pouch is obliterated, and so, by preventing the formation of adventitious bands or peritoneal fossæ, they eliminate the possibility of post-operative strangulation of the bowel. They further point out that such an operation lessens the extent of the plastic operations on the vagina and renders them less severe. This method no doubt largely eliminates the risk of intestinal obstruction, but the fact that an abdominal section has to be performed still remains. Some of those who took part in the discussion pointed out that no one operation could be expected to give equally good results in all cases and that a careful selection of cases and of operations specially suited to the conditions present was more likely to give good results than a blind adherence to any one particular method. This is sound sense.

The discussion served to show that a great many gynæcologists are content to practise only plastic operations on the vagina in cases of prolapse and that when properly carried out these operations give a very high percentage of cures. Any operation which is performed for the cure of this condition is the best which tends to reproduce as far as possible the original anatomical condition of the parts, and for this reason plastic operations on the vagina as a whole will always be more anatomically correct than any form of uterine fixation. It would seem that whenever possible in women still of child-bearing age plastic operations on the vagina alone should be performed, and that forms of ventrofixation should only be carried out, if at all, in women past the menopause and in cases of very severe procidentia.

THE EXISTING INSTITUTE OF STATE MEDICINE.

A COPY of a memorandum sent on behalf of the Council of the Royal Institute of Public Health by its President, Lord Leverhulme, to the Minister of Health has reached us. The memorandum is in the form of a report from the Executive and Finance Committee, signed by its chairman, Surgeon Rear-Admiral Sir P. W. Bassett-Smith, which was adopted by the Council on June 23rd. Its main feature is a protest against the omission in the recently published report of the Post-Graduate Medical Committee, abstracted in our columns last week, of any allusion to the Royal Institute of Public Health. The memorandum includes a historical summary of the activities of this body, resulting in the statutory recognition of Diplomas in Public Health in 1886, in their adoption as necessary qualifications for medical officers of health in 1888 and 1889, and in the recognition by the General Medical Council of a special curriculum of post-graduate study for these diplomas. In 1905 the Council, recognising the inadequacy for post-graduate purposes of the training in public health offered by the undergraduate schools, and the desirability of centralising post-graduate training in one institution, proceeded to found and equip laboratories and to arrange courses of instruction. These courses have since been recognised by every medical examining board in the United Kingdom as qualifying for admission to examination for the D.P.H. The Institute has been recognised by the University of London as a public educational institution and its course for the degree of M.D. in State Medicine is approved by the University. The Council adds evidence that the Institute has had under consideration for some time proposals for developments on the lines now suggested by the Post-Graduate Medical Committee, to which no representative of the Institute was summoned to give evidence. The memorandum ends with a request that the Minister of Health should consider the desirability of building up an Institute of State Medicine on the foundations already laid by the Royal Institute of Public Health rather than the creation of a new Institute.

THE adjourned discussion on "The Problem of the Private Clinic System in Great Britain," will be held at the Royal Society of Medicine, on Monday, July 4th, at 8.30 P.M., the President, Sir John Bland-Sutton, in the chair. If thought desirable the following resolution will be moved:—

> "That in the opinion of this meeting the time is ripe for the formation of Group Clinics in this country, and that sympathetic encouragement should be given to them by the profession and by its governing bodies."

Annotations.

"Ne quid nimis."

PROFESSIONAL IMMORALITY ON THE STAGE.[1]

THOUGH the presence of a medical practitioner is often invoked in comedy, a play devoted entirely to medical questions and written by a medical man is certainly a rare occurrence. The stage hardly seems the place for an essay on medical deontology, though "The Right to Strike" was in substance such an essay. Dr. Rothschild's work, however, is a live drama, and as performed on the semi-classic boards of the Gymnase last week justified its appearance at the theatre which, in French literature and histrionic art, comes next after the Théatre Français and the Odéon. Baron Henri de Rothschild left the world of finance to become first a doctor in medicine, then a philanthropist, and many model dwellings for artisans are due to his generosity and much public encouragement in works of sanitary reform. And now he has achieved a large measure of success as a dramatic author under the pseudonym of André Pascal. Some of André Pascal's plays have already been presented in London, Monte Carlo, Brussels, as well as in Paris.

"The Caduceus" has had a difficult birth. When read to the company at the Odéon the players were scared by the subject, no less than by the vivacity and frankness in the telling of ugly truths. In the middle of the controversy we had the war; and, after the war, it became necessary to alter those portions of the play satirising the frivolity of society ladies, for, during the war, they had surprised the world by their devotion. This is shown in the revised version now given at the Gymnase. The story tells how an unscrupulous medical practitioner, without means or scientific success, but with the genius of self-advertisement, raises himself to social eminence and wealth in an incredibly short time, being financially backed by usurers and dealers in furniture and bric-a-brac. This person, Dr. Revard, at the opening of the play is instructing his secretary to write to a practitioner as follows: "Answer that I want a fee of 6000 francs for myself, and that, as this is the first affair, I will give him a commission of 50 per cent.; but for other affairs which he may bring me I will, in future, give him 20—no—say 30 per cent. He is an intelligent fellow and should be encouraged." The secretary then prepares to leave the room, but is called back to make sure this answer will be sent by telephone and not committed to paper. Thereupon a discussion arises, for Dr. Durieux, an old fellow student who overhears the dictating, is shocked at the paying of commissions out of medical fees. Dr. Revard agrees; first and foremost, he answers, it is well understood that there is to be no dividing, and no commissions to intermediaries. We are only entitled to ask a fee that will enable us to pay our assistants, he allows. But, in practice? The client rarely bargains over the sum the operator requires; on the other hand, eight times out of ten he refuses to remunerate the medical attendant, though the latter has the heavy responsibility of recommending an operation and of selecting the operator. The client generally thinks he has paid quite sufficient for the operation without bothering about accessories, therefore, says the specious Dr. Revard, certain surgeons are glad to assist beginners. Such, in brief, is Dr. Revard's professed code; in fact, he thrives on commissions, and, through four acts, the dishonourable methods by which his success is obtained are exposed till they lead up to the final and dramatic catastrophe.

One of the advertising dodges is the operation performed before the kinematographer for fashionable ladies and sensation-hunting reporters. Then comes the passage which the experience of the war caused to be altered. The old and highly honourable Prof. Godfroy thus protests:—

> "Come, my friends, let us agree for once. Before the war the public wanted new performances, something more sensational, and certain practitioners did not hesitate to admit to the tragic sanctuary of surgery fashionable society women in search of some diversion."
>
> The Marchioness: "That was odious!"
>
> Prof. Godfroy: "Then the world tragedy burst upon us. Women now knock at the door of our hospitals, impelled not by morbid curiosity but by the sentiment of duty! I render homage to their admirable devotion.

Prof. Godfroy, when consulted by a wealthy, dissipated American lady, Mrs. Watson, tells her quite plainly that there is nothing really the matter with her, but she had better go to bed earlier and take a cold bath in the morning. Dr. Revard, on the other hand, delights this same lady by making love to her and prescribing pink and perfumed baths. The need of money, however, leads him to perform a bogus operation upon her, and he kills his patient. After this catastrophe Prof. Godfroy again appears, this time as the Nemesis of the play, and denounces Dr. Revard in these energetic words:—

> "Yes, there is no higher title, no title more sacred than that of Doctor of Medicine. But that title must preserve its prestige. There must not be among those who bear it any elements of corruption. We must not permit certain individuals to become, among our young men who are so wholesome and generous, elements of corruption. Thus if among us there should be a black sheep it is our duty—the older ones—to sacrifice it. That is why I have come here. Madame Watson was not your first victim, but I swear to you that she shall be your last."

Dr. Revard ends with an effort to redeem his reputation. He commits suicide, but in such a manner as to demonstrate the action of a toxin which his friend Dr. Durieux hopes may provide the means of checking septic poisoning. There is no doubt that the play is thrilling, and points a good moral. But we should be sorry to think that the medical profession requires such an obvious lesson. The play is published in a special supplement of *L'Illustration*.

THE PHYSICS AND CHEMISTRY OF COLLOIDS.

A BOOK, written in German, on the preparation of colloids by Prof. Svedberg appeared in 1909. Recently he has published an interesting short monograph[1] dealing with the nature of the processes leading to their formation, in which a most difficult subject is made unusually clear. Colloids or disperse systems may be formed in two ways, by condensation or by dispersion. In the former method, matter is brought together within a smaller boundary surface than before; in the latter, the matter is dispersed so that the specific surface is increased. In some cases the processes of condensation and dispersion may be combined. Superficially the electric arc method of producing colloidal solutions of metals is one of dispersion, but in reality it belongs to the second group, since it consists in the vaporisation of the metal and its subsequent condensation. It is thus essential to know the state of the system immediately before the formation of the disperse phase. There are only a few cases of dispersion, such as emulsification of fats and hydrocarbons, occurring in the homogenisation of milk, and the grinding of material to minute particles. Most processes leading to the formation of colloids are those of condensation. The simplest is condensation in vacuo, as exemplified by the dark layer on old incandescent electric lamps; the metal has been vaporised and condenses as a film of particles on the glass. Similar deposits can be made in a neutral gas and the gas may be exchanged for a liquid, as in the case of the submerged arc where the liquid around the arc is converted to gas. The production of disperse systems in liquids and solids usually involves a chemical reaction such as reduction, oxidation, or double decomposition. Here again we can have as alternatives volume condensation and surface condensation. Photograph reactions are generally volume condensations; surface condensation takes place between two reacting solutions at their surface only. Prof. Svedberg deals with the various experimental details which have been used to elucidate the processes. Many of these, for instance, the formation of spray, smoke, and volcanic dust, are of great practical importance.

THE DIAGNOSIS OF FOREIGN BODIES IN THE AIR- AND FOOD-PASSAGES.

IT is within the experience of every laryngologist that foreign bodies may pass through the larynx with the production of the most trifling symptoms which may readily be overlooked in children, and even in adults. Foreign bodies, especially if of a non-absorbent character, may remain even in the lung for a long time without producing symptoms, and Dr. C. H. Carroll's interesting case recorded in THE LANCET of June 18th shows how the practitioner must not be put off his guard by the absence of history of swallowing anything unusual. Sooner or later, however, symptoms arise, but the circumstances which might suggest the aspiration of a foreign body have by that time been forgotten by the patient, and many cases have been treated for such affections as chronic bronchitis, bronchiectasis, or pulmonary tuberculosis for prolonged periods in some of whom the correct diagnosis has only been disclosed by post-mortem examination. A correct knowledge of the symptomatology of foreign bodies in these regions is obviously, therefore, of the highest importance, but the relative rarity of the cases in the experience of any one observer has made systematic study a matter of great difficulty. Dr. Chevalier Jackson has recently published such a study based on 789 cases from the Bronchoscopic Clinic of the Jefferson Medical College of Philadelphia.[1] He lays stress on the diagnostic value of a history of initial laryngeal spasm, but states that a foreign body may pass right through the larynx into a bronchus without producing any laryngeal disturbance. If sudden death does not occur, the initial spasm passes, and a certain degree of toleration is established; but foreign bodies do not often remain latent in the larynx for any considerable time, for reactionary swelling usually produces enough dyspnœa to call for examination. In the trachea foreign bodies are usually movable, and their movements can be felt by the patient, while the vibrations may be palpated or heard with the stethoscope. Cough is apt to be paroxysmal and very severe, and a sudden shutting off of the expiratory blast and of phonation during paroxysmal cough is almost pathognomonic of a movable tracheal foreign body; there is usually dyspnœa due partly to the bulk of the foreign body and partly to traumatic subglottic œdema. Jackson describes an "asthmatoid wheeze," heard at the open mouth, not at the chest wall, in cases of tracheal and bronchial foreign body; in the former it is usually louder and lower in pitch. Pain is uncommon, but may occur and be accurately localised by the patient.

It is in the bronchi that foreign bodies are most likely to remain latent for long periods. There is often a protracted, delusive, symptomless interval, and the time of inhalation may be unknown or forgotten. Cough and purulent expectoration ultimately result; periodic attacks of fever, with chills and sweats, and followed by increased coughing and the expulsion of a large amount of purulent, more or less foul material are so nearly diagnostic of foreign body as to call for exclusion of this probability with the utmost care. All the symptoms of tuberculosis, emaciation, clubbing of the fingers and toes, night-sweats, and hæmoptysis are in most cases simulated with exactitude, even to the gain in weight by an outdoor regimen. But tubercle bacilli have never been found at the clinic in association with bronchial foreign bodies, which therefore do not cause, but only imitate, pulmonary tuberculosis. The distinctive taste of metallic or organic bodies may be noticeable to the patient, and offensive sputum should always suggest a foreign body. Sudden complete obstruction of one main bronchus does not cause noticeable dyspnœa, provided that its fellow is functioning; but complete obstruction of a bronchus is followed by rapid onset of symptoms. The physical signs usually show limitation of expansion on the affected side, impairment of percussion, and lessened transmission of breath sounds: signs which may lead to an erroneous diagnosis of empyema. In cases of non-opaque foreign body, radiographic examination is still of great value; the signs are those of an acute unilateral obstructive emphysema, and include increased transparency on the obstructed side, displacement of the heart to the uninvaded side, and downward displacement of the diaphragm with marked limitation of its movements on the obstructed side. Organic foreign bodies, such as nut-kernels, and especially pea-nuts, cause a severe general toxæmia and local reaction, which is more marked in young children and may be fatal within 24 hours; to this affection Jackson has given the name "arachidic bronchitis." He strongly advises that all cases of chronic chest disease should have the benefit of a radiographic study to exclude bronchial foreign body, that negative opinions should never be based on any but the best plates, and that even then there will occasionally be need for diagnostic bronchoscopy. In the œsophagus, foreign bodies are more easily diagnosed; lateral and antero-posterior radiographic plates should be taken, and, when the body is not "radiopaque," screen examination of the deglutition of a barium mixture, or barium capsule, is of great value.

We would recommend the study of this careful and thorough monograph, not only to laryngologists, but, and more especially, to general physicians and practitioners; for if, in obscure cases of pulmonary disease, the possibility of foreign body is regularly borne in mind, the errors of diagnosis described by Dr. Chevalier Jackson will less frequently occur.

TRANSMISSION OF THE ENCEPHALITIS LETHARGICA VIRUS.

IN a recent communication,[1] Levaditi, Harvier, and Nicolau demonstrated that the virus of encephalitis lethargica is transmissible from the mother to the fœtus, in the case of rabbits. A pregnant rabbit was inoculated with the virus and died 11 days later. The brain showed characteristic histological changes, while the brain of the fœtus examined appeared normal, but a portion of the latter injected into a healthy rabbit produced a typical encephalitic infection. The above observation confirms the view that the virus of encephalitis lethargica can be present without producing any gross histological change, as McIntosh and Turnbull found in the Derby epidemic. In addition it proves that the virus can pass through the placenta and infect the fœtus, thus lending considerable support to the idea that in a certain number of these cases of encephalitis in young infants the infection is congenital in origin. The work may thus have a bearing on the treatment of cases of pregnant women suffering from encephalitis lethargica. When the infants are born alive and subsequently develop symptoms of the disease, infection from the maternal nasal secretions or through the milk cannot always be excluded, but the experimental findings of MM. Levaditi, Harvier, and Nicolau suggest that transmission in utero is at least a possibility.

INDUSTRIAL DERMATITIS.

SKIN eruptions among industrial workers are of frequent occurrence and come under the observation of busy practitioners almost daily. The extent to which they prevail may be judged from an estimate made in one industry only that approximately 25 per cent. of all machinists exposed to oils are or have been affected with dermatitis.[1] The inclusion of dermatitis and ulceration of the skin produced by dust or liquids in the schedule of diseases for which compensation must be paid under the Workmen's Compensation Act, 1906, gives a further and legal significance to this group of affections. Hence, the publication in America of three important papers based on considerable research into the causation of skin affections among workers exposed to oils cannot fail to be of interest. The conclusions arrived at by the different workers are not dissimilar.

The subject has previously received attention from our own medical inspectors of factories and one of their investigations (the importance of which seems to have escaped the attention of the American investigators) throws particular light upon the whole matter, because the peccant material—pure olive oil—was unadulterated by anything else.[2] The observer, Dr. E. L. Collis, concluded that the trouble was caused by the oil dissolving the natural fats, palmitin and stearin, from the skin which then becomes dry; cracks follow through which microbic invasion occurs, setting up dermatitis. Here is presented the first simple stage in the process. McConnell, in reporting upon an investigation among printers,[3] after placing on one side all possible influences such as health, physique, family history, or exposure to infection, remarks that "one significant fact was very prominent: all persons suffering with dermatosis were found to have dry skin—that is, skin either partially or wholly devoid of natural oiliness; whereas those persons without eruptions have oily skin. This dryness of the skin is the only differentiating factor found to exist with any degree of constancy among the men so affected."

When the oil, as in the case of cutting oil in engineering shops, is mixed with fine metal chips, these chips by causing small punctures facilitate the introduction of microbes.[4] When, as in the case of printers,[3] there is exposure to inks containing "driers" and to a fat solvent like benzol, the dyes in the ink aid in damaging the dry skin and retard healing. When dirt and oil block the small glands at the root of the hairs, folliculitis, somewhat different in causation, may complicate the case.[5] The degree of natural oiliness in the skin of different individuals varies considerably, and where it is most pronounced the tendency to dermatitis is least. Careful bacteriological investigation[6] has failed to incriminate the oil as the necessary carrier of infection, even though it may act in this way; indeed, certain paraffin oils, produced in the process of pressing paraffin wax, encourage bacteria breeding,[4] but the bacteria have no power for evil until they have secured ingress to the skin.

The position may be briefly summarised as follows: (1) Oils of all types and other fat solvent fluids are liable, if they come in contact with skin for some time, to produce dermatitis; the underlying cause is desiccation with subsequent cracking of the skin. (2) The exact form of dermatitis which results depends on the infective organism or organisms which obtain access. (3) The organisms are not usually present in the oil, but exist on the human body; therefore the dirtier the skin the more readily is it infected. (4) Prevention depends first upon cleanliness, and secondly upon restoring the dissolved fat by anointing the skin with such a mixture as equal parts of lanolin and castor oil. (5) Treatment consists in removal from exposure and entire rest to the affected skin by covering it with a flexible paint, such as is used in treating burns.

AN ACQUISITIVE SOCIETY.

STRAWS show the way wind blows; at present there is a movement in the wind of popular thought in regard to social reorganisation. Whether this movement will prove to be stimulating to the health of the body politic or not, the medical profession, which is so intimately associated in its work with the whole community, cannot afford to disregard any indications. A new book,[1] by Mr. R. H. Tawney, is perhaps part of the wind rather than a straw pointing its direction. Its author has previously published his main thesis in a pamphlet "The Sickness of an Acquisitive Society," but in his present volume he sets forth his case more completely. Briefly, the contention is that property should always carry with it responsibility, and that property which carries no responsibility is a drag on the wheels of social progress. He gives the term Acquisitive Society to a community which acquires property and, neglecting all duties, merely asks "May I not do what I like with my own?" Among such property, called Functionless Property, are grouped mining royalties, ground rents, and shares in limited companies; rewards here are divorced from services; a class of pensioners upon industry is created; and in consequence those who labour, but who do not by their labour command their full reward—that is, the great majority of mankind—are degraded. Acquisitive Society reverences the possession of wealth; a Functional Society would honour, even in the person of the humblest and most laborious craftsman, the arts of creation, and would fix the idea of function as a principle, upon which all remuneration should be based. The reader will peruse with interest the methods by which Mr. Tawney proposes to reconstruct industry and commerce. He seeks to convert industries into professions which always recognise the relation between payment and effective service; to this end he sees promise in movements like that of the Guild of Builders which eliminates dividends, provides for all men "on the strength" when work is slack, and supersedes profit-making employers. He advocates a fixed rate of interest on industrial capital, instead of unlimited profits with limited liability, as a first step towards lightening the strangle-hold of capital upon labour. Only faint praise is given to nationalisation, as that term is usually understood.

The chapter dealing with the brain-worker and the growth of an intellectual proletariat is one of great interest. Under the organisation of industry advocated, the brain-worker might be expected to come into his own. The medical sociologist cannot fail to be deeply interested in the cogent arguments put forward; but he will find no appreciation given to the tenet that every community possesses the social organisation it deserves, an organisation which represents its capacity for healthy thought. He will find himself then wondering whether a healthy nation is not the first requirement for obtaining a wholesome organisation, and whether the finest of organisations on paper would not in practice fail if applied to an unhealthy community. The crucial questions are: Would a healthy organisation convert an unhealthy community into a healthy one? Or would a healthy community convert an unhealthy organisation into a healthy one?

A STUDY OF ARTERIO-SCLEROSIS.

Difficult and controversial as are the pathological problems involved in the study of the condition of diffuse hyperplastic sclerosis, its clinical relations and associations are even more complex and elusive. Dr. Geoffrey Evans[1] having come to the conclusion that the underlying process in this, as in other forms of arterio-sclerosis, is inflammatory, proceeds to study the clinical conditions associated with it—namely, raised blood pressure, cardiac hypertrophy, cerebral hæmorrhage, and chronic renal disease, more particularly in their bearing upon his conception of its inflammatory nature. In studying the post-mortem records of heart-weights in a 20-year period at St. Bartholomew's Hospital, he found that, where chronic heart and lung conditions could be excluded, a post-mortem weight of 15 ounces and over generally indicates the presence of diffuse hyperplastic sclerosis. On the other hand, this condition can be found without cardiac hypertrophy in exceptional cases. In regard to raised blood pressure, Dr. Evans makes the statement that a persistent systolic blood pressure of 190 mm. Hg or over is evidence of diffuse hyperplastic sclerosis; indeed, he believes that it is the only adequate clinical sign of diffuse arterial disease. In other words, he regards the clinical condition to which the term hyperpiesia has been applied as in reality the expression of diffuse hyperplastic sclerosis. He suggests that syphilis is a cause of an increased mortality in cases with hypertrophied hearts about the age of 45, and he believes that syphilis is a cause of cardiac hypertrophy and diffuse hyperplastic sclerosis, with a maximum effect at about this age. On an analysis of the records of cases of cerebral hæmorrhage, investigated by him, he finds suggestive evidence that two types of arterio-sclerosis may occur in association with it, one being diffuse hyperplastic sclerosis, the other a more patchy or local form, probably of senile type. The most important part of the clinical side of his paper is that dealing with chronic renal disease. He states that he has found evidence of inflammatory change in all the kidneys he examined which were the subject of extensive disease. He claims that this fact supports his contention that the arterial disease associated with renal disease is also inflammatory in origin, and he would solve the riddle as to whether the kidney disease is the cause of the vascular changes or vice versa, by the thesis that both are the simultaneous result of a common cause, though this may be of varying kind and intensity in different cases. He suggests that in acute conditions the epithelial reaction dominates the picture, and that when the process induced by the pathogenic cause is chronic, epithelial and vascular changes both result and therefore coexist, while in very chronic cases only the vessels suffer. In such manner the different appearances in chronic diffuse nephritis, in true chronic interstitial nephritis, and in arterio-sclerotic kidneys are to be explained. Dr. Evans's views are to some extent speculative, although based on a careful and ingenious analysis of his laborious histological, post-mortem and clinical investigations. Their chief value lies in their suggestive character, for they open up fields for fresh research. Further elucidation may be expected from the biochemical investigation of renal function in medical diseases of the kidney which is now being pursued by several workers.

THE INTERALLIED NEUROLOGICAL CONGRESS IN PARIS.

The second annual Interallied Neurological Congress, organised by the Société de Neurologie of Paris, has been held and was from first to last a complete success. Delegates attended, officially or otherwise, from Great Britain, United States, Italy, Belgium, Portugal, Spain, Denmark, Sweden, Holland, Switzerland, and China. The subject announced for discussion was "the Parkinsonian syndromes"—i.e., paralysis agitans, idiopathic and symptomatic. Four sessions of some three hours each were devoted to this topic, yet neither the supply of speakers nor of material showed any sign of running short. It is safe to say that some ten years ago a discussion of paralysis agitans of this length, and width, would have been quite impossible. But the disease is one which has come prominently to the fore within the last decade and that for two main reasons. An immense impetus was given to the study of the subject of extrapyramidal motor disease by the work of the Vogts and of Kinnier Wilson in 1911–12; from that time the syndrome of the corpus striatum and the whole conception of striatal disease passed from mere speculation to the rank of a new and properly grounded chapter in neurology. Only those who have followed the matter can have any idea of the vast literature on the subject that has since accumulated; as was generously said of British neurology at the Congress, progressive lenticular degeneration, a striatal disease par excellence, has gone right round the world, and if the contributions of British origin can still be numbered on the fingers of one hand, they have been made by the score on the continent and in the United States. Paralysis agitans has naturally benefited by this renewal of interest, for, like many other extrapyramidal conditions, it is characterised by a combination of involuntary movement with muscular hypertonus, and its resemblance in several cardinal features to progressive lenticular degeneration—an affection with a known pathology—has furnished an obvious guide for neuropathologists. Henceforth, all search for the cause of Parkinson's disease in muscles, peripheral nerves, motor nerve end-organs, and Betz cells, must be abandoned. The second factor in the development of the subject has undoubtedly been the remarkable number of post-encephalitic cases of symptomatic paralysis agitans; with the fresh appearance of epidemic encephalitis in one country after another the crop of Parkinsonian cases has been ever increasing.

At the Congress M. Souques gave a clinical demonstration of some dozen patients, mostly young people and some mere children, every one suffering from symptomatic Parkinson's disease as a sequel to encephalitis, and their appearance in a row facing the large audience was peculiarly impressive. No one can doubt that so definite and specialised a clinical picture must correspond to an equally defined pathological entity. What is this pathological basis? According to the work of Ramsay Hunt, the Vogts, Lhermitte, Foix, and others, degenerative or destructive changes in various cell- and fibre-systems of the corpus striatum and its efferent connexions to the corpus luysii, locus niger, nucleus ruber, and other mesencephalic cell-groups, are followed by the appearance of rigidity and involuntary movement and these changes are declared to be the essential pathological feature of Parkinson's disease. Lhermitte, employing the method of Casamajor, has demonstrated the existence of fibre (myelin) degeneration in paralysis agitans in the efferent (striofugal) systems to the above-mentioned nuclei, and Foix, more particularly, has found degenerative changes in the locus niger in every one of several cases of the affection. The Vogts have recently published an account of their examination of no less than seven cases of the disease; in all of them a noteworthy degree of atrophy of the putamen-caudate and to a less extent of the globus pallidus, with loss of cells and fibres, was found; there was a general rarefaction and absorption of tissue in the vicinity of the blood-vessels in these basal nuclei—a kind of état criblé. Thus, though there may be as yet no precision or exactitude in regard either to the site or the nature of the pathological alterations, no doubt can be entertained of the general localisation of the morbid changes. Further research ought to be devoted as much to the physiological mechanisms involved as to the morphology of the lesions. There is room for more intimate study of the problem both of muscular hypertonus and of involuntary movement, and the syndrome of paralysis agitans is not to be divorced from others which are equally characterised by rigidity and one or other type of hyperkinesis. Lesions of the cerebellum, for example, and mesencephalic lesions, may reveal themselves by disorders of tonus and by involuntary movement, and the same is true of the optic thalamus. Only by taking a large view of the question can we arrive at informative results. The widespread interest aroused in neurological circles at home and abroad apropos of the corpus striatum and its syndromes is calculated to prove less useful than will otherwise be the case if due attention is not paid to the occurrence of combinations of dystonia and involuntary movement that are shown to be independent of structural lesions of that part of the brain.

THE GOLD MEDAL OF THE ROYAL SOCIETY OF MEDICINE.

AS we have already announced, the first award of its Gold Medal will be made by the Royal Society of Medicine to Sir Almroth Wright. The gift of the medal has been instituted as a method of recognising original discovery in medicine or other allied sciences. It will be awarded triennially, and the prize can be given for the practical application of the results of previous investigations of other scientists as well as for new and personal work. This is a thoroughly sensible admission that the finest contributions to the art and science of medicine must be founded on the work of predecessors. All such progressive work is original in the best scientific sense, and the Royal Society of Medicine has been wisely inspired in its declaration of the fact. Sir Almroth Wright will deliver a lecture before the Society on Wednesday, July 6th next, when the annual general meeting of the Society will take place and the medal will be awarded. The design for the medal is the work of Mr. E. Carter Preston. It bears on the obverse the figure of Hygieia bestowing a wreath upon Research, typified as a figure carrying a lamp. At the bottom of the obverse side of the medal is the legend " Non est vivere sed valere vita." On the reverse we have Æsculapius supported by Chiron, the wise centaur, his master. Below the centaur we see the serpent of Æsculapius and the bow of his father Apollo. On the field are the words " Finis coronat opus."

ROEHAMPTON AUXILIARY HOSPITAL.

LAST week we published an account by Dr. C. Jennings Marshall of the admirable work of the arm-training centre at Roehampton, in which he dwelt on the demoralisation and resentment of a man who suspects that he has been fitted with a badly-fitting artificial limb and the psychological effect of the provision of a comfortable and useful one. Queen Mary's Convalescent Auxiliary Hospitals at Roehampton, for sailors and soldiers who have lost their limbs in the war, are this week celebrating the sixth anniversary of their opening. Over 41,000 officers and men have suffered amputations of the leg or arm owing to the war and, though other centres for the supply, renewal, and repair of artificial limbs have been organised by the Ministry of Pensions, Roehampton has dealt with a very large proportion these service men. 1324 officers and 21,339 O.'s and men have passed through the hospital, patients, since June 28th, 1915; readmissions of all ranks for second limbs and repairs amount to 55,707, and this figure does not include the 16,518 cases dealt with by post. 8453 men have received training in instructional workshops opened in 1916. Of these the employment bureau has found work for 4987, and has made arrangements for further training for 4166.

In 1918 arm instruction classes were instituted, and many who had found artificial arms an encumbrance were taught how to get the utmost work, and indeed enjoyment, out of their use. Dr. Marshall, in his article, emphasised the keen interest taken by the men in their own manipulative progress—not confined to progress in work, but also in sport. The sight of those who in a few weeks are able to play cricket and golf must indeed be stimulating to the neurasthenic who enters the hospital despondent as to his chances of getting any fun out of life, even should he ultimately be able to work. The in-patient accommodation at Roehampton has now been reduced to 200 beds, for which it is hoped to get permanent endowment, but since between 50 and 60 men attend every day for major and minor repairs the out-patient department is still busy, and likely to remain so. An account of these hospitals will make one of the most inspiring chapters of the medical history of the war.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

IT is too early to judge the results of the appeals on behalf of the metropolitan hospitals which were made from pulpits in London and elsewhere by ministers of all denomination last Sunday; but never was the need of our hospitals greater than it is at the present, and it is earnestly to be hoped that, when the totals are announced, we shall learn that an aggregate sum has been collected surpassing that of any previous year in the history of the Fund. In the past the appeal has been made on the grounds of a common humanity, but the events of recent years have added new impulses to the conscience of the people, and we may fairly look for their expression. The part which our houses of healing played in winning the war, and in ministering to the needs of its victims, will surely have its influence over the purses of many. But what is necessary is permanent effort as well as a quick and special response. Sir James Paget, wisest and best of men, nearly 70 years ago said: " If in all our improvements of our means of life, only half the trouble had been taken to prevent or remedy the future evil, that was taken to attain the present good . . . . our state might have been far different." The report of Lord Cave's Committee shows that the voluntary system of hospital support must be maintained and indicates the way in which the money can be provided. The Government has responded promptly—though to only half the amount mentioned as an early requirement—by voting £500,000 in aid of deficiencies in the funds of the voluntary hospitals during the year, and the Minister of Health has expressed the opinion that the balance should be found by voluntary effort. This should be forthcoming from a national and coördinated effort, and it would be a splendid incentive to such effort if the Metropolitan Hospital Sunday Fund collection this year proves to be an outstanding one in the annals of hospital charity.

THE honour of knighthood has been conferred upon Dr. John Walton Browne, surgeon to the Belfast Ophthalmic Hospital.

MR. A. W. Sheen, C.B.E. (Military), M.S., F.R.C.S., has been appointed Professor of Surgery, Welsh National School of Medicine from Oct. 1st, 1921.

INDEX TO "THE LANCET," VOL. I., 1921.

THE Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, will shortly be published in THE LANCET.

CLINICAL UNITS:
THEIR PURPOSE AND ACHIEVEMENT.

BY C. M. WILSON, *M.C.*, M.D.LOND., F.R.C.P.LOND.,
PHYSICIAN TO OUT-PATIENTS AND DEAN OF THE MEDICAL SCHOOL, ST. MARY'S HOSPITAL.

IT is no part of my present purpose to set forth the causes which led to the creation of the Clinical Unit System. I am rather concerned with rescuing from a brief experience extending only over a year and a half such lessons as may be helpful to those who wish to contribute to the permanence of the Unit organisation, and that may indicate the lines upon which its successful development may be best assured. The deficiencies which it was designed to meet are plainly set forth in the writings of Osler and of Sir Clifford Allbutt, in the reports of the General Education Board of America, in the report of the Royal Commission on University Education in London of 1913, and in the contributions of Sir George Newman. It was planned to provide leisure for research and for meeting the growing educational demands on the time of physicians and surgeons, to provide the future heads of English medicine with a more scientific training, to protect their waiting years from the tyranny of routine and from financial anxiety, and to other ends which will presently appear.

The Teaching of Experience.

The Johns Hopkins Hospital in America was the first to put into practice, in 1913, the Clinical Unit System. In England, owing to the war, it was not until 1919 that the Board of Education granted the same opportunities to four of the London schools: St. Bartholomew's, St. Thomas's, the London Hospital, and University College Hospital. In the spring of the present year the London (Royal Free Hospital) School of Medicine for Women applied for and received a Unit in Gynæcology and Obstetrics, and later Clinical Units in Medicine and Surgery were recognised at St. Mary's Hospital. It is only possible, therefore, to enter a provisional opinion, which may have to be modified in the light of a fuller experience of the Unit organisation. There are incidentally good reasons for caution in extending this system. The cost to the State is considerable, and to the schools it may even be prohibitive, while it cannot be said to have been proved as yet that teaching, care of patients, and additions to knowledge are all so much better under the full-time scheme that every medical school should hasten to fall into line. We are, too, far from certain that we have more than a few among the younger clinicians who are willing and capable of the direction of these Units. There are not wanting signs that the supply of these men is limited, and that if the demand be immediately increased a very different type of man will have to be called upon. And quite apart from personnel, not every school is fitted for a Unit, either in laboratory equipment or in the educational motive without which the life of the Unit can only be brief, troubled, and unproductive. We wish for assurance, before committing the State to a larger outlay, that our schools number among the more promising of the younger generation sufficient men who are willing to work for university rewards, rewards that can never hope to rival the prizes of a worldly career on the latter's own ground. There is, however, no reason to suppose that men will not be found who, in order to procure ideal conditions for clinical teaching and investigation, will be willing to renounce monetary rewards. For a full-time clinical chair appeals to the idealism that is more common than many know. But, though it is probably a libel to say that good men will never become Directors since they can make more in practice, it is a totally different proposition to expect that the man who has so ordered his life that he may engage in practice will be ready to forgo the advantages of which he has had experience for the prospective rewards of a life which has no sharp outline in his mind.

Units may be mere pretentious names. They may mean no more than an insurance taken out by an insecure school against impending dissolution, a comfortable sinecure for an indolent man who lacks the energy and vitality to conquer in the competitive world. This is the old system under another name, the same thing in a new dress. We have to ask, have we in fact got any fundamental addition, have we a man of ideas as Director? It is well for the reputation of the system that the number of schools in which it will be tried at first will be limited by financial considerations. These Units are not to be regarded as a mere addition to clinical teaching, something that will atone for the irregularity of attendance and the broken service that is given to the pursuit of knowledge under our present system, not as new facilities for tutorial instruction to be bestowed upon those schools which, by their tradition and size, wear an air of permanence. They should be granted as the spear-head of an active, restless, and progressive school, when, and only when, the university authorities are satisfied that a suitable man is forthcoming as Director.

But if we are satisfied that these conditions obtain, what are the advantages that a school may reasonably anticipate if it should adopt units? As physicians we are impressed with what we do not know, but at least the worker in the Unit enjoys the comfortable assurance that in a scientific sense he knows more about his patients, and that if he does not add his quota to knowledge it is not for lack of opportunity. He has a new freedom: he is no longer obliged to devote the better part of his days to the support of his family by some form of practice. He has leisure. That men can be too busy to stay to meditate, that they should pass their days and know nothing of "the fruitful hours of still increase" is a hard decree. In fine, Units can do no more than give the right man a fair chance to carry out good work. This is the issue. Can we, without the Unit organisation, reap the advantages of a body of physicians who engage in research, and if we cannot, is it well with education and with our ways of adding to knowledge?

We shall, then, jealously guard this new freedom which the more hopeful among our younger clinicians are likely to enjoy. We shall plan, too, so that we do not exchange the tyranny of one form of routine for another, that the time of the Unit is not eaten up with the "treadmill of the classroom." If all students pass through the Unit under the personal supervision of the Director, it is idle to expect of him original and productive work. And if we make of the Director no more than a coach we have defeated our own ends. The system, born in hope and faith, will have achieved nothing but harm. But, if we guard this precious leisure of the Unit worker, we shall foster a mood, a frame of mind, very friendly to fertility: the Director will value his office not alone for its facilities for teaching, but also for its unique opportunities of learning.

For the student Units may mean no more than expert coaching—this is the danger. He may value greatly what from the educational point of view is of little account. Wherefore we must look to the wise provision that entrusted these appointments to an outside body with university ideals to protect the system from abuse. Where it is prudently administered the system may give the better type of student a deeper insight into the intricate ways of disease. It can scarcely fail to widen his outlook over the whole field of medicine and surgery. And if the Director is a reflecting man, his constant contact with students must sharpen their curiosity, quickening the legitimate ambitions of their calling.

The patient, too, can but benefit when diagnosis is built up on the more elaborate methods which are only possible with the leisure which the Unit confers. These advantages will, however, be dearly bought if students are led by the Unit organisation to look on patients as so much clinical material. For it is the spirit of units that matters, a false step in the beginning may vitiate everything. To this point we return when we come to consider whether the Director should be allowed private practice. It is significant in passing that ward sisters like the Unit system, though it throws increased burdens on them and on their staff.

The Possibilities of the Unit System.

These are the more obvious reflections which our experience of Units suggests. But we cannot come to a decision as to the merits of the system on such a simple basis, and I am of one mind with Prof. Janeway, Director of the Medical Clinical Unit in the Johns Hopkins Medical School, who, in a brief account of his first year's stewardship rendered to the General Education Board, wrote: "The real success or failure of the plan will be best appraised from the careers of the men who now are receiving their training on the staffs of such departments." I agree with him that "if the professorships of medicine in our best schools ten years from now are being filled from the ranks of these men, and under their influence our medical clinics are becoming actively investigative university departments, then the whole-time system will have demonstrated its effectiveness." This is the crucial test, and we must await the result. But we shall wait with no misgivings, for if the right spirit inspire the Units they will be schools for teachers in the broadest acceptance of that term. The teacher must assimilate new knowledge before he can add it to the diet of the student. I would take a parallel from the ways of nature and the life of the fields. The plant needs nitrogen, but cannot use the nitrogen of the air until it is made into nitrates; only the clover family, by virtue of symbiotic bacteria, can make use of the raw material so that it is available for its own use and for the use of other plants. The teacher is the clover, taking the abundant raw material of new knowledge and changing it to the form in which it can be used by students.

Under the present system the waiting years are swallowed up in routine work by the faithful performance of which promotion is earned. I have faith that Units will break this down. There has always been a certain amount of intercourse between the leaders of the profession in different countries, but practically none between the younger generation. In the years when such intercourse counts most we do not join in discussion with the hopeful of other lands. It should be possible to effect some system of exchange by which American universities would send to us young men to work on the staff of the Units, while by reciprocal arrangement the more curious of the new generation would receive at an impressionable age the quickening impulse that comes of travel and the assimilation of new ideas. We may hope that those who have been responsible for the visits to America of certain of the Directors of Units will be able to arrange that the Assistant Directors, upon whom so much of the future of Units depends, will receive like opportunities. We shall at least require of the new generation that it is not content to live apart from all the rest in its own town or city—that if we work in London we shall remember that there are fair cities beyond Jordan, and that in modern times the provinces have perhaps contributed more than their share to English medicine.

And then there is the evil of premature publication which leads men to think in terms of opportunism and saps their intellectual integrity. We are in haste to "trumpet abroad our acquirements." Here Units which remove the motive may cure the disease. Most of us write too much and too soon, unmindful of the counsel of St. Chrysostom, beloved of Osler: "Depart from the highways and transplant thyself into some enclosed ground, for it is hard for a tree that stands by the wayside to keep its fruit till it be ripe." We may ask of the Units another spirit, the spirit in which our cathedrals were built through the centuries, our tapestries woven, and our manuscripts illuminated, in the faith of all exquisite work that is not hurried nor slipshod. In this regard it is singular to note in the regulations governing the appointment of the Directors at one school that they are required to reside within a certain distance of the hospital. If we must be for ever laying down regulations I would have them live in the depths of the country, but I would be not unmindful that if you ask for the things of the spirit you cannot by rule and regulation make sure of receiving them. The hour is scarcely kind to the art of the physician. There is something in the time and in our tastes that is not friendly to leisurely observation. We ask that these workers should pass tranquil days, a little away from the dusty paths of life, so that clinical medicine may receive a measure of the service that is freely given to other sciences. We would not have the Director hurried out of thought, but that without losing touch with the realities of the world in which he must play his part, he shall say to himself the words graven on Hazlitt's sundial, "Horas non numero nisi serenas." There is another aspect. Of the factors which count as the most influential in moulding the student, nothing is so important as the mute example of the lives of their teachers, and it is surely not without profit that we should have in our midst a body of men whose lives are given to something other than the lucrative rewards of private practice. There is held up before students an alternative to monetary prizes, and that alternative is the Unit system.

There are, too, more utilitarian services that Units can perform. They furnish an opportunity of reorganising the out-patient department of a hospital, so that it may be of greater value in studying the beginnings of disease. At the present time if assistance is rendered to the out-patient physician it too often takes the form of a sorting department, so that in the issue no case has access to the physician unless stamped by the physical signs of advanced and incurable disease. In our haste to teach signs we throw away more precious opportunities of learning. On the other hand, the criticism has been directed against the Unit organisation that the class of case admitted to the Unit wards lacks variety because many of the most interesting cases in the wards of a consulting physician are sent to him by practitioners, and if the Director does not practise, his wards are no different from those of a general hospital without a teaching school attached. The remedy lies in the development of the out-patient department of the Unit, and in sending away the patient so satisfied that he becomes a recruiting agent. There is far too much delay before a patient is seen, and in more ways than one the out-patient department from the human point of view is out of date. It profits nobody that the working woman with a large family should wait three hours to get her medicine repeated, with a perfunctory word or two on the part of an exhausted physician. Where out-patients are treated in a kindly and considerate manner they multiply. The reform of the out-patient department bristles with difficulties. We need a kind of social service in which there is a medical counterpart to the lady almoner and a follow-up department that will accompany the patient to his home, with a view to checking the out-patient turnover, the large number who draft from one hospital to another. But the Unit will never lack material in London. On the contrary, there is a real danger that it may have too much. If the Director is asked to take charge of a large number of beds he will be fortunate to escape a new form of routine. Surely the value of experience is "not in seeing much, but in seeing wisely."

In measuring the benefits which it is customary to ascribe to the Unit organisation we shall not be put off with fine phrases. Do Units, for example, bring about in fact as well as in name a closer union between clinicians and workers in the laboratories? There is a desire for a more intimate relationship. Are Units the proper means for securing that end? Are we on the clinical side more ready and more willing to make use of knowledge born in the laboratory, and are they, who have hitherto been cut off from the inspiration of clinical phenomena, finding, as we bring them into the wards, new subjects for inquiry? Do we stimulate each other? It is early days to enter judgment. It would appear, however, that the physician is becoming more conversant with what can, and what cannot, be done in the laboratory. He does not so frequently refer a problem to his scientific colleagues when he would hold his hand if he had possessed but a rudimentary knowledge of the possibilities of their technique. It is not irrelevant that at St. Mary's, since units were inaugurated, a club has sprung into being, attended by the personnel of the units and by the staff engaged in the pathological, bacteriological, and other services. At these meetings the subject is approached from every angle, and the club appears to fulfil a useful purpose. Should the Unit do its own routine pathology and bacteriology, or should the work be carried out in the pathological department of the hospital? We have no doubt the latter is the better course, and that the temptation to make the Unit self-contained is to be resisted.

In the practical working of the Unit organisation there are two problems that recur again and again and press for a solution. Should the Director give all his time to the duties of his office, and not engage in private practice, or should he be allowed a limited amount of private practice, devoting the greater part of his time to the Unit? And what should be the relation of the Units to the rest of the staff of the hospital?

Whole-Time or Part-Time.

Some will have it that a sharp break with the old system is required, that only whole-time appointments are worth considering. Others, for example the physician and surgeon nurtured in another school, who are of a mind to get the best out of both worlds, are as certain that the Director of the Unit should be allowed to practise. The man who belongs to neither camp can only envy the facility with which in either case a decision is reached. If the Director be allowed practice, if he be a man of parts and personality, he will doubtless prosper, and his thoughts and perhaps his person will fly away to the dusty traffic of the busy consultant's life. And if he be without these gifts he is no man to vitalise this new way of teaching. Moreover, research and the sober reflection in which it has its being scarcely thrive in the hurry and press of practice. So much is plain enough. On the other hand, there is a real danger, although it is less obvious, that the whole-time official debarred from practice will grow into an academic figure whose usefulness is threatened by the evils which afflict a whole-time service, that this man, deprived of the quickening impulses which contact with the outer world brings, will become isolated, and that his influence and very teaching may lose their touch with realities. He will miss the humanising influence of practice, and his mind may shrink, since it lacks the widening sympathies which contact with the outer world excites. But if he is so fortunate as to escape the creeping paralysis that to younger men is the bane of the academic life where the competitive stimulus gives place to security, his later years will be enriched with the rewards of his unusual opportunities. Frankly I am less impressed with the alleged scientific advantages of practice, though it cannot but be valuable to see a patient in his environment. In America a compromise has been effected. At the Johns Hopkins Hospital the full-time staff are allowed perfect freedom to see private patients. They have their consulting rooms at the hospital, and the fees taken are added to the funds of the Unit organisation. In 1913 such fees amounted to $10,000, while it cost $110,000 to maintain the full-time services in medicine, surgery, and pediatrics. From this it might appear that the clinical teacher freed from the necessity of earning fees finds little that is scientifically or educationally valuable in private practice. But we shall accept that conclusion with caution, bearing in mind that it is not in human nature to engage in private practice for the benefit of an institution, and that incidentally it is in direct conflict to the experience of Sir William Osler, the integrity of whose judgment is not open to question. Further, we have to remember that this was the first year of this arrangement at the Johns Hopkins Hospital, and that the Directors, though famous in their art, were in the main imported from other cities. We believe that Unit workers should be allowed to see private patients at the hospital, and to take fees. Carried out at the hospital the system protects itself from abuse, and in America, as we understand, it works happily. Further, no other system seems to bring permanent peace and contentment to the Unit personnel and to provide a proper field of recruits for vacant directorships. This provision would go far to satisfy the considerations that weigh with many men who will not at present allow their names to be put forward as candidates for Unit appointments. They are not so much reluctant to give up the emoluments of practice as to embark upon a system which is admittedly on trial. They do not care to burn their boats. If they were able to return to practice in five years' time in the event of Units at their schools being abolished, the field for these appointments would be greatly strengthened. This applies particularly to surgery and gynæcology and obstetrics. Nevertheless, though there are sound reasons for their caution, I look for another spirit in the man who will make of the Unit a vital thing. If he possess imagination and the qualities without which success must be wanting he will not dread failure. He will know that if he can make of this organisation a living addition to medical education, he has little to fear from passing phases of financial stringency. He will go forward to his task with a good faith in his mission, and with a modest belief in his own power to accomplish it.

Relation of Unit Workers to the General Staff.

It were impertinent on my part to combat the foolish sayings of those who persist in looking upon the personnel of the Units as a race apart, immune from the frailties and temptations of a consulting physician. They are simply different persons discharging different functions, and this separation of function is required by the increasing complexity of science and social life. The consultant has duties which the Unit worker cannot usurp, his practical views are a useful antidote to the idealism of the full-time worker. They are sister services, or if there must be a question of seniority, then the general consultant belongs to the senior service. Certainly there is no antagonism between the scientific and the practical physician, and the relation between them can only be solved on the basis of experience. One thing is already clear. The Unit must be an integral part of the organisation of the hospital, it should in no circumstance be allowed to become an extraneous growth. It will be responsible for the coördination of the teaching of the general staff, but of that teaching it will itself form but a small fraction.

Meanwhile Units have their own pitfalls and traps for the unwary, and it may be profitable to dwell for a moment on the particular dangers that lie in the path of the system. The peculiar merit of the older regime was in the intimacy which existed between student, teacher, and patient. There is a danger that in the attempt to raise schools to a university standard we shall have fewer and larger institutions, and that the popular and accepted teacher, who is not unlikely to gravitate to the Unit attached to such schools, will be surrounded by a horde of students following him round his wards. Now those who are seeking true educational ideals have as much reason to distrust academic eloquence and the arts of the orator as any other form of persuasive speech which appeals now, as always, rather to the emotions than to the intellect. They discriminate clearly teaching and talking. It must be the constant aim of the Unit not to substitute large classes for the intimate methods of the older system, but rather to carry this intimacy a step further. At the London Hospital the Director and his three assistants each devote one whole morning every week to not more than one or two clerks, who in this manner profit by a personal guidance in the management of their own cases, which in the past has been given only by the house physician. There are dangers, too, of the effect of routine in this new life of the worker as great as any in the past. We have but one safeguard against these and kindred perils. It rests in the knowledge of the type of man who is needed as Director, and in the determination to appoint as Director none other.

The Future of the Units.

Excessive anger against human stupidity is itself, as Lord Bryce has reminded us, one of the most provoking of all forms of stupidity, and we shall do well to remember that criticism of the Unit system may proceed not at all from prejudice and ignorance, but solely from an honest review of the character and history of English medicine. We shall profit more by listening to the strictures of the opposition, than from many of the ill-considered eulogies of Units that have been heard in debate. If they are a natural step in the development of medical education, an evolutionary step, they have nothing to fear from passing political phases, or from the opposition which all new things must face. At the worst they may disappear temporarily, to reappear later in another and better form. But if they are only an ill-digested experiment on the part of certain theorists, then their end cannot be long delayed by the zealous idealism of youth. In the main it is true that we cannot be in a position for at least ten years to appraise the advantages and disadvantages of Units. Meanwhile they may come to an untimely end for one of two reasons. Firstly, economists, and just now they are rightly in the ascendant, may ask for a justification of such expenditure at a time like the present. And this may happen either in respect to the grant by the State, when the agitation will be political, or in the councils of the school, when it will have its roots partly in the impatience of certain of the older clinicians with a system with which they dispensed in their day, without, as they think, incurring serious disadvantages: partly in a more rational if somewhat shortsighted agitation founded upon the embarrassment of the schools' finances by this new call. Secondly, the men to staff the Units may not be forthcoming. The Unit personnel will, in that event, be overshadowed in point of achievement by other members of the general staff. It will then be asked, not without reason, why so much money should be expended with so little apparent result. If, therefore, we desire to secure for the Units a fair trial, if we wish to persuade men to suspend their judgment for a decade, we have to convince the more impartial that something has been added to medical education. For if at any time they should decide without bias that the Units supply in essence nothing that is not provided by the existing staff, the days of the experiment are numbered, and a precious opportunity will have slipped through our hands. Accordingly, men who have faith in the Unit system are concerned that no verdict should be pronounced upon it until it has had a fair trial, and they are keenly alive to the fact that they can only achieve their end by the appointment of Directors who are equipped to pilot the system through these troublous years. It is, therefore, of no little moment to crystallise in our minds the essential qualifications that fit a man for this difficult task.

The Qualities Needed in a Director.

Clearly he should be capable of wise and devoted leadership, for his task is no less than to bring out his school the practical idealism which is latent in it. I shall not dwell in the first place on his capacity organisation and research, though they are all-important, since they are less likely to be overlooked when they appear than the qualifications which he must possess as a teacher. With regard to those qualifications plain words are in season. Primarily the Director should *wish* to teach. He needs a zeal that is constantly fed by the stimulus of new knowledge. Then, if he be the man we seek he will borrow from his daily contact with the more hopeful among students the elixir of teaching life and it is very necessary that he should do so. For when teaching is a mere matter of routine, it is only talking, the man is a phonograph, there is nothing vital in him. Again, it is the very essence of the Unit system that he should be given the opportunity to remain a student, and if this is necessary to vitalise his teaching it is no less fitting in his relations with students. We shall call to mind the warning of St. Thomas à Kempis that "learned men are very willing to seem wise and to be called so." No pose as of a master should mark the teacher among his disciples. He is their comrade, one of the pack. Above everything the Director must hold his students. If he fail in this nothing else matters, and if we wish for assurance that he will not in fact so fail in the future, we shall require proof that he has succeeded in the past.

With regard to research, where a candidate possesses the necessary credentials no difficulties will arise. But where the right man is not available we may be tempted to be put off with the second best. There may grow up a tendency to take from his laboratory a work-a-day fellow, without ideas, without any educational purpose whatever, with indeed nothing to offer but his own technique, and to place him in charge of wards, so persuading ourselves that the problem has been solved. No wiser plan this than to take your mediocre physician or surgeon and to put under him a laboratory, buttressing his ignorance with a junior assistant or two conversant with technical methods, and then to claim him as our scientific physician armed at all points for the great adventure. The whole art of medicine is in observation, and if the Director has not that art he is out of place in his office. How shall we teach students to observe if we have not learnt ourselves? And is a man to come by this most difficult art by the simple means of taking him from his laboratory and placing him for a few months in charge of a ward? "Clinical teaching is not easier than laboratory teaching, it is more difficult; clinical research is not easier than laboratory research, it is more complicated." It is hoped that in the Unit organisation the Director may remain during his working life in close touch and sympathy with the resources which the accessory services are constantly placing at his disposal. Certainly it may reasonably be required of him that he add to knowledge, but if he appear to have the mental outfit that holds forth a reasonable prospect that he will in fact do so, we shall do wrong to tether him to any one line of investigation. If he adopt the Hunterian motto, "Do not think, but try," we shall be content; we want no more of him.

It is fitting here that we should speak of the problems of the Director of the Surgical Unit, and their relation to research. His task is more difficult. He may be an arresting teacher; there are many such. His technique perhaps is immaculate; it is not uncommon. What can he add that his colleagues do not already give? As I think, not a little. The estrangement which gradually grows up between the practising consultant and the preliminary and intermediate sciences is perhaps deeper, at any rate more visible, in surgery than in medicine. We shall ask of the Director of the Surgical Unit that he act as an intermediary. If, for example, the office had been in existence a decade since, we might reasonably have required of him that he should work out the physics of gastro-enterostomy, the factors that determine success or failure, so that we might not have been compelled to wait for the experience derived from many after-histories and not a few failures to formulate in our minds the indications and contra-indications for that operation. He has a virgin field, and his harvest will ripen before that which his medical colleague has sowed is apparent above ground. We seek for the ideal, but if its fulfilment belongs to another time let us feel assured that we have found in him, who in the phrase of the Iliad is to be the nurse of men, those attributes of leadership which we recognise when seen and acknowledge as admirable in other walks of life. Where a Unit is seen to languish, where its very existence is the target of criticism, there assuredly is this vital man wanting. And so we come to our final and most pressing need, the capacity for leadership and for organisation, a need which has been grievously neglected. The Unit organisation is a scaffolding, and the building has yet to be raised up. We ask of the architect that however he may lean on the past he will bring to his work an individual offering. And we shall require of him not solely contributions to research, but also an addition to those larger educational conceptions and developments for which a unique opportunity is furnished by the Unit system. And quite apart from this opportunity the Director in a more modest way may be very helpful to those who are struggling with the educational problems that cluster round the reform of the curriculum; he will, too, have something to say about the more intimate correlation between preliminary, intermediate, and final subjects. And if he should possess a full and deep acquaintance with the great principles of the fundamental sciences upon which our art is based, I confess to hoping that in the atmosphere of the Unit organisation he will not neglect the study of the humanities.

In the task that he has set himself the Director will find his youth very precious to him. Harvey complained in his day that "few men above this critical age (40) seemed able to accept the doctrine of the circulation of the blood." Those among us upon whom that fate is beginning to cast its shadow may hope that the receptive age is nowadays a little longer, but put it as you will this affair of Units is a young man's task. He will get from the elders the best of counsel, but the faith and the driving force and the forward view must be his, and without them he is lost. To take a man past middle age and to ask him to inaugurate a new system that is foreign to all the ways of his life can lead nowhere, and it is idle, therefore, to demand of our candidate that he should come to his post with an assured fame, a name built upon years of research. We have rather to ask of authority that it should put the stamp of its recognition upon merit a little before and not after the public verdict. And this is the more necessary, for we shall ask of this man tasks of organisation which might be distasteful to, and even foreign to the talents of, one whose ways have long been set in a particular groove.

In our doubts the tendency to turn for a Director to a pale and ineffectual type, the scientific recluse who has fallen out of the ranks of the competitive world, is so strong, and so fatal to the system, that I wish to stress again those qualities of temperament and character that are needful to the well-being of the whole undertaking. It is trite to assert that the system cannot exist long if the Director has no hold upon students, but in actual practice the axiom often meets with only lip service. An appointment to a Unit falls vacant, and the candidates' credentials are freely canvassed. We reject straightway the pure clinician, and as rightly will have nothing to do with the man whose experience is confined to laboratories. Then we are in trouble. Our Admirable Crichton is nowhere to be found, and in our perplexity at last we hit upon one who appears to have a foot in both camps. We scrutinise his contributions to knowledge and weigh the value of his published research, and then if they are passably decent our task, we feel, is done. But we do not stop to inquire what imprints this man has left on his school and on his contemporaries, how far he is fitted to govern and direct. He has to steer his craft in its first voyage across strange seas, and by all appearances he will have heavy weather. Whatever other qualities he may possess that seem likely to do justice to his lofty ideals, he must have the force of character, the drive, the will to conquer in a school that may be only tepid in its welcome to his aim and purpose.

He will not be allowed to build altogether in peace, and he and his assistants in the Unit will find their salvation in Lord Morley's Essay on Compromise, with its just discrimination between compromise in the field of action and compromise in the field of thought. He will learn that while pliancy may be fitting in the first it may be near to treachery in the last. There is great need for toleration, not only that a new experiment may receive a fair trial, but also that we may approach the task in hand in the spirit of detachment befitting a great educational adventure. So only can we build not amid the distractions of personal controversy, but with the help and counsel of the elders of our calling. When sorely perplexed by the difficulties which beset the advocate of Units, and in doubt as to the real aim and purpose that we should set before us, I confess I turn for guidance not so much to the present as to the past. Everything that we want is to be found in the writings of the late Sir William Osler and of the Regius Professor of Physic in the University of Cambridge, happily still with us, though it is natural that we should think of him as of the past, for his voice has the detachment which we are not wont to associate with the daily strife and turmoil of the present. The justification of Units, if they have one, is indeed not based upon any new set of conditions, but has its roots in the orderly development of English medicine: they are but a step in its evolution, which at the present time may appear to us rather more important than it is. The aim of medical education is no different from that of education in general, and they who have looked long upon wide horizons are best equipped to counsel those of us who can only offer for the harvest of experience the enthusiasm of youth.

If literature is the effective agency of cherishing within us the ideal, it may be that in the passage of time this development in our schools will come to play the same part in medical education. Meanwhile those whose happy fortune it is to labour in this field shall have no fear that if the Unit system should come to an end their sowing will have no reaping. For if this happen some new and better plan must surely grow in its place, and the soil that has been lovingly tended will bear the richer harvest, of which harvest others in good time shall have the gathering.

TUBERCULOSIS.

German Views on Surgical Tuberculosis.

AT the forty-fifth session of the German Surgical Society many and conflicting views were expressed as to the treatment suitable for surgical tuberculosis. Prof. Bier[1] pushed his advocacy of conservatism in the treatment of tuberculosis of the bones and joints to a point that drew much criticism from several of his colleagues. In his opinion operative treatment was indicated only when amyloid disease threatened, sepsis supervened, or when severe disease of the joints was complicated by destructive pulmonary tuberculosis. Even when osseous foci of disease were extracapsular he no longer interfered with the knife, and he did not consider it invariably necessary to remove sequestra by operation even when they were septic. His belief in the spontaneous resorption of sequestra had the proverbial red-rag-to-a-bull effect on some of his fellow surgeons. He did not consider subluxation of the knee an indication for resection, but for gradual readjustment by extension and postural treatment. He left cold abscesses severely alone or limited interference to aspiration without the injection of any foreign substance. His objections to opening tuberculous abscesses applied also to those derived from the spine, and his attitude towards Albee's operation for immobilisation of the spine in Pott's disease was frankly hostile. The three remedies which he considered most important were sunlight, passive congestion, and the internal administration of iodine; even severe forms of surgical tuberculosis could be cured, in his opinion, by this trinity. He had some suggestive views on pigmentation of the skin—a process which he compared with the reaction of the body to protein therapy. This pigment, he thought, was derived from the colouring matter of the blood, and was the outward and visible sign of protein metabolism. The specific action of the sun on the affected joint was not due to local processes, but to a general reaction by which the defensive properties of the organism were mobilised. As for passive congestion, its effects were excellent, provided the dosage was suitable, and cold abscesses and the too luxuriant growth of granulation tissue were held in check by the internal administration of iodine. He had used tuberculin with considerable success in his out-patient practice, but he had seen no benefit from Friedmann's remedy towards which he had at first been favourably biased. Another point over which he differed profoundly from several of his colleagues was the harmfulness of dressings which immobilised the limb. He kept patients with disease of the lower limbs exposed to the sun in bed or with dressings which only relieved pressure without immobilisation; as soon as pain had vanished he advocated systematic exercises.

---

[1] Deut. med. Woch., April 28th, 1921.

Other speakers were König, of Wurzburg; Garrè, of Bonn; v. Eiselsberg, of Vienna; Müller, of Rostock; Borchardt, of Berlin; and Sauerbruch, of Munich. The latter remarked that on one point all the speakers seemed to agree; of the great value of sunlight, even in the lowlands, all were emphatically convinced. König, who would not subscribe to Bier's rigid conservatism, referred to an *enquête* addressed to 22 leading surgeons whose answers showed that there were three chief schools of thought in this matter. The extreme conservative school was represented by Bier and nobody else, although many surgeons recognised the value of conservative treatment early in life. The intermediate school advocated operative treatment provided conservative treatment had failed after a fair trial. The third school had a penchant for resections and amputations. König himself was in favour of the operative removal of foci of disease in bone, particularly when they threatened to invade a joint; if this happened he advocated resection, and he operated at once for severe] mixed infection. He threw an interesting sidelight on the subject by referring to the opposition of insurance societies to conservative treatment on account of the time it took and of the psychic deterioration entailed. Garrè disclaimed any love for passive congestion and iodine medication, and was not ashamed to confess that he injected iodoform and glycerine into cold abscesses, and that he could not dispense with dressings which immobilised the limb. He considered it advisable to dig out sequestra when they were near a joint, and he did not think it possible that definite subluxation of the knee-joint could be corrected by extension only. Winding up the discussion Bier toned down some of his original expressions of opinion, and he made the concession that plaster-of-Paris dressings might be used provided they were made to be taken off easily. Within the past seven years he had performed only about 12 major operations for tuberculosis of the bones.

Treatment of Pulmonary Tuberculosis by Deycke-Much Partial Antigens.

The literature of partial antigen or partigen treatment is already prodigious, and if quantity is in any degree an index of quality there must really be something in this method. Unfortunately many writers advocating this treatment feel more inclined to indulge in speculative digressions and in recapitulations of complicated theories than to give a plain account of results seen in the flesh. In a recent paper[2] Dr. M. Landolt, Director of a sanatorium in Barmelweid, rations himself with commendable frugality in the matter of Deycke-Much theories, and devotes himself chiefly to the technique of the treatment and the results obtained thereby. With regard to technique he greatly prefers the intracutaneous to the intramuscular injection, as the latter is apt to provoke an obscure reaction which is not betrayed till the scales show loss of weight. He also makes a point of using a separate syringe for each partigen, and for each concentration of the same partigen. Reviewing his results he shows that 75·4 per cent. of his 122 partigen-treated patients were discharged as "much improved," whereas only 47·6 per cent. of the 82 patients treated by subcutaneous injections of old tuberculin could be put in this category on discharge. A comparison of the gain of weight in these two classes was also much in favour of partigen treatment. But, as Dr. Landolt admits, the comparison was hardly just to old tuberculin, for this was given subcutaneously, and it is conceivable that, had it been given by intracutaneous injection, the results might have approximated more closely to those of partigen treatment.

The Costs of Tuberculosis.

In a paper[3] by Dr. Louis I. Dublin and Dr. Jessamine Whitney a new attempt has been made to calculate the economic cost of tuberculosis to a modern community. Their studies were instituted by the Metropolitan Life Insurance Company and the National Tuberculosis Association, and were, to a certain extent, conducted on the lines already followed by Prof. Glover. They find that wage-earning white males lose 3·5 years in all or 7·6 per cent. of their entire expectancy. Coloured males and females lose about five years of life. It is also calculated that a loss of one year of life is equivalent to a loss of not less than $100 in national wealth. As tuberculosis cuts approximately two and a half years from every individual, the loss per person is at least $250. This, in a population of approximately 106 millions, represents a loss of over 26 billion dollars. Nor does this calculation include the very large additional losses entailed by long periods of ill-health due to tuberculosis. This paper is a powerful plea for combating tuberculosis for economic as well as for humanitarian reasons.

The Rôle of the Tonsils in Pulmonary Tuberculosis.

According to medical travellers returning to Europe from a tour of inspection of the leading clinics in the U.S.A., the tonsils are at present looming large on the American horizon as foci of disease. It remains to be seen whether the wholesale shedding of its tonsils by a civilised community will greatly reduce the incidence of diseases such as rheumatoid arthritis, but there is already a considerable amount of evidence to damn the tonsils as a potent source of disease. In a recent paper by Dr. James Gerret van Zwaluwenburg and Dr. G. P. Grabfield,[4] a plausible case is made out for linking up primary tuberculosis of the tonsils with that form of pulmonary tuberculosis which begins with an apical pleurisy and is later manifested by tuberculous infiltration of the apices of the upper lobes. Their evidence is mainly rontgenological. Rontgenologists are familiar with a shadow at the apex of the lung which is generally interpreted as a sign of localised thickening of the pleura, and is spoken of as a "pleural cap." The main thesis of this paper is to prove that this

---

[3] American Review of Tuberculosis, April, 1921.
[4] American Review of Tuberculosis, March, 1921.

"cap" is of tuberculous origin, the result of a downward extension of tuberculosis from the tonsils and through the cervical lymphatics. At the Department of Pathology in the University Hospital of Ann Arbor, Michigan, all the tonsils removed for various reasons were examined for tuberculosis, one section of each tonsil being taken so as to include almost all the crypts. Sixteen persons whose tonsils showed tuberculous foci were subjected to an X ray examination of the chest, and all with but one exception showed a "pleural cap." The X ray examinations of the chests of 27 persons whose extirpated tonsils were found to be free from tuberculosis revealed only three cases of a "pleural cap," and in none of these three did this "cap" amount to more than a relatively fine line without demonstrable evidence of tuberculosis in the underlying lung. To ascertain the frequency of this "pleural cap" in other conditions the 318 chest radiograms taken over a typical three months' period were scrutinised. Unfortunately the figures given in the text do not tally with the corresponding figures given in an adjoining table, but one fact seems to emerge with clearness; in at least 10 per cent. of all the radiograms there were signs of an apical pleuritis as the sole indication of tuberculosis. The authors suggest that the pleura offers a considerable barrier to the further progress of this descending infection, and that the disease is frequently arrested at this point. They have succeeded in demonstrating the quiescence of the denser type of "pleural cap" over a considerable period, and they consider that the denser and the more sharply defined this shadow the more harmless it is. On the other hand, they view with suspicion those "caps" which are lacking in density and which show irregularities on the visceral surfaces, for these features may indicate inadequate cicatrisation and the possibility of propagation of the disease along the connective-tissue elements of the lung. If these views are confirmed by other investigators a definite advance in our knowledge of the ætiology of pulmonary tuberculosis will have been made.

Wildbolz's Auto-Urine Reaction.

Wildbolz's test for active, as distinct from latent, tuberculosis has not of late had a good press. He believed that in the urine of the subjects of active tuberculosis there are specific tuberculous antigens, the existence of which can be demonstrated by the intracutaneous injection of the patient's concentrated urine. The patient himself and any other person with active tuberculosis would, he argued, give a positive reaction, as shown by a small, indurated swelling, whereas no such change would be found if the patient's tuberculosis were no longer in an active stage. But Dr. H. Trenkel,[5] who has subjected the test to a searching examination at Dr. Amrein's sanatorium at Arosa, is very sceptical as to the specificity of the test, and he suspects the so-called positive reaction as being nothing more than a "salt reaction." In six controls—persons whom he had no valid reason for regarding as tuberculous—the reaction was positive, and only in two such controls was it negative. It was also negative in some cases of active tuberculosis. The cogency of his criticism is accentuated by his claim that he has faithfully followed every detail of the test as described by Wildbolz. Dr. R. Offenbacher[6] has investigated this test at the hospital of the Jewish community in Berlin, and, like Dr. Trenkel, he adds force to his criticism by insisting on the strict orthodoxy of his technique. Only in three out of 20 cases of clinically active tuberculosis could he provoke a positive reaction, and he could establish no correlation between the outcome of the test and the condition of the patient. He is, however, less whole-heartedly sceptical than Dr. Trenkel, and he admits that there may be some connexion between the reaction and the activity of the disease. Dr. E. Liebhardt[7] is another critic who blends faint praise with discouraging figures. Working at the communal hospital at Nurnberg, he has experimented with the test in 51 cases, only a proportion of which were tuberculous. His 11 non-tuberculous controls invariably gave a negative reaction, and so far an important substantiation of Wildbolz's claims seems to have been made. But the reaction was also negative in four out of 19 cases of active pulmonary tuberculosis, and in several other cases in this class the reaction was so slight that it would have been missed and labelled "negative," but for a pin's head nodule which was palpable but not visible. Dr. Liebhardt's observations on the subtleties of the test and the interpretation thereof may possibly afford a clue to the conflicting evidence of other workers. Dr. H. Alexander,[8] who is chief medical officer of the Seehof Sanatorium at Davos-Dorf, has subjected Wildbolz's reaction to a varied series of tests. Altogether he has repeated the test 159 times, and among his 91 cases, including several non-tuberculous controls, he found much to confirm Wildbolz's claims. But in as many as 15 cases of definitely active tuberculosis the auto-urine reaction was negative. It was also negative in 12 out of 13 persons showing no clinical evidence of tuberculosis. He is inclined to regard the reaction as specific, and when it is positive he considers the evidence in favour of active tuberculosis to be quite strong. A negative reaction, on the other hand, is, at present, of comparatively little value; and it seems that he could establish no relation between the reaction of the skin to an intracutaneous injection of tuberculin and Wildbolz's reaction. He found the reaction was considerably weaker with urine concentrated by evaporation in an open water-bath than with urine concentrated by evaporation in vacuo. He also never obtained a positive reaction with unconcentrated urine. In its present stage the test can evidently not be relied on, and it seems doubtful whether so complex a substance as urine can be expected to lend itself to such a delicate and discriminating test as that which Wildbolz has devised.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

INDIGENOUS DRUGS OF INDIA.

SEVERAL debates took place in the Legislative Council of 1918 on the question of Ayurvedic and Unani drugs and the indigenous drugs of India. The speakers pressed for an investigation of these drugs, urging among other things that Ayurvedic and Unani medicines were as efficacious as those of the British Pharmacopœia; that the indigenous systems were cheaper than Western medicine; and that careful investigation would discover a large number of very valuable but hitherto unknown remedies.

Dr. Koman's Reports.

As a result the Madras Government appointed Dr. M. C. Koman, an Indian medical man attached to the Medical College, Madras, to carry out an investigation, and after more than two years work three reports have been published which throw considerable light on the various points raised in the Legislative Council. As a preliminary, visits were paid to Ayurvedic pharmacies and dispensaries, and after collecting the most important drugs and compound preparations, Dr. Koman experimented with these on suitable patients in the wards of the Madras General Hospital. It was quite impossible in the period to investigate more than the therapeutical actions of the medicines, as a well-equipped laboratory and staff would have been required in order to make a pharmacological and toxicological research successful.

Since the time of Ainslie (1826), who first created an impetus for the study of indigenous drugs of India, there has been, Dr. Koman states, a cont-increasing interest manifested by the members of the medical profession in India in the investigation of indigenous drugs. Warden and Hooper's work, the reports of the Indigenous Drugs Committee, and the work of Waring, Mohideen Sheriff, W. C. Dutt, and K. L. Dey, prove that all important indigenous medicinal plants have already been investigated, and Dr. Koman adds: "in vain have I attempted to find any drug or medicine whose reputed marvellous properties are shrouded in mystery or have not been already known." In fact, he found, with few exceptions, the practising *vaidyas* and *hakeems* generally unversed and unintelligent, though industrious and well-meaning, and nearly all evinced a firm conviction and belief in the intervention of evil spirits and offered many curious and absurd rules for averting their machinations.

Principles of Ayurvedic Medication.

The properties of drugs are, according to them, correlated to the hypothesis of the three humours, wind, bile, and phlegm, which forms the basis of the ætiology, diagnosis, prognosis, and treatment of disease in Hindu medicine. This, as Dr. Koman says, might have formed a working basis in the ancient days of Maharishis, and before Harvey discovered the circulation of the blood, but it cannot hold good against the rational scientific physiology and pathology of the present day. Inquiries regarding specific or general treatment for cases of cerebral apoplexy, locomotor ataxia, the different forms of Bright's disease, cirrhosis of the liver, kala-azar, &c., elicited the fact that these diseases were beyond the scope of successful treatment. There seems, indeed, little if anything for us to learn from the methods of treatment followed by the *vaidyas* and *hakeem*. At the same time Dr. Koman produces figures to prove that the cost of maintaining an Ayurvedic dispensary is much the same as that of maintaining an ordinary dispensary, whilst in addition the Ayurvedic system, with the exception of cataract couching, confines itself to the treatment of medical diseases.

A few drugs proved to be of considerable value, and Dr. Koman recommends that these might be incorporated into the Pharmacopœia of the Presidency hospitals, although a good deal of further work should be done and considerably more experience gained before they can be universally commended. It is also suggested that, as a guide to medical students, the important Indian drugs should be included in the course of lectures on materia medica at the Madras Medical College.

Included in Dr. Koman's list are: (1) *Hydnocarpus inebrians*, a potent drug in ameliorating the complications of leprosy; (2) *Kirmani* (*Artemisia maritima*), a substitute for santonin; (3) *Chempullanhi* (*Colycopterus floribunda*), an efficacious anthelmintic; (4) *Boerhavia diffusa*, a good diuretic in cases of anasarca, the result of Bright's disease. In a second appendix is given a list of 40 drugs or compounds found to be "useful," but not as effective as medicines already in the B.P. They are given as they are cheaper and more easily obtained than their B.P. equivalents.

Towards an Indian Pharmacopœia.

The Government in reviewing Dr. Koman's reports consider it worth while to continue the experiments with the drugs which have been found to be of value, with a view to their gradual incorporation in the Pharmacopœia of the Presidency Hospitals. There is little doubt, however, that the reports do not meet with the approval of those who asked for the investigation. In spite of Dr. Koman's nationality, they are convinced that his training in Western medicine prejudiced him from the beginning, but all those who are acquainted with the investigator will endorse the compliment paid him by the Government when they anked him for carrying out a difficult task with ommon tact, industry, and patience under very vourable conditions.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Humanitarian Warfare and Bullet Wounds.

Dr. Pafucan recently read a paper at the Medical Union, Bucharest, on bullet wounds in their relation to humanitarian warfare, in which he stated that in the recent war the Serbians and Italians used old-style rifles, which were, however, excellent as regards the safety of the rifle carriers. Their bullets were of larger size and higher velocity than those of the Russians. Moreover, the Russian bullets were pointed, and penetrating wounds caused by them healed very well, whereas the Serbian, Austro-Hungarian, and Montenegrin bullets were very destructive of tissue. No tissues could withstand the impaction or in any way deviate the course of the Russian bullet; the wound is usually so cleanly incised that no pieces of clothing are carried in. The bone is rarely splintered, except in cases where shrapnel is used. The blood-vessels were very often injured, and Dr. Pafucan reported several cases of aneurysm of the popliteal as well as of other arteries. Many of the nerve trunks were attacked. Although these wounds usually healed easily and without reaction, meddlesome examinations were sure to react unfavourably on the course of healing. Pus appeared only in those cases where the tissues around the path of the bullet were invaded. Another complication arose from the frequently large cicatrices and tough adhesions. Out of 496 gunshot wounds there were 27 cranial, 21 being through the substance of the brain. Deep penetrating lesions in this region were not accompanied by any destruction of the bones of the skull; the latter was observed only in the superficial wounds. Six of the cases were accompanied by paralysis of the arm and leg; two presented the symptoms of cortical epilepsy evidently due to pressure and removed by operation. The general results of wounds of the lungs were rather favourable, all of them, with two exceptions, being penetrating. There was hæmoptysis in 22, subcutaneous emphysema in four, and extensive hæmothorax in one. Dr. Pafucan had observed 43 cases of abdominal trauma, all of which were penetrating wounds; of these only five died, chiefly owing to neglect of treatment; one death was caused by peritonitis. There were several penetrating wounds of the liver, spleen, and kidneys.

Disorders of the Heart in Adolescents.

Dr. Goldenberg, chief medical inspector of the Middle Schools, has written a small pamphlet on the above subject, in which he states that he has found comparative hypertrophy of the artery walls not uncommon in older children and at puberty, but the accompanying blood pressure is not materially increased, although there may be palpitations and a sense of oppression in the chest. The cause is a "growth hypertrophy," as a rule, although masturbation has been accused of the results. Lack of dilatation of the heart, lack of murmurs, normal size of the liver, good health otherwise, and absence of aggravation of the symptoms by physical exercise, render an organic lesion improbable. Children are particularly prone to arrhythmia, brought on by the slightest causes; the harmless arrhythmia is distinguished by the full and powerful pulse beat, the diastole alone varying in length. This form of arrhythmia also subsides if the heart action becomes accelerated, as the abnormally long diastoles are then shortened. This infantile type of harmless arrhythmia may persist beyond puberty, and give grounds for alarm if casually discovered first in a young pregnant woman. Arrhythmia due to actual organic disease is generally the result of extra-systoles: the latter may be accepted as suspicious of a genuine organic heart lesion; but they may also occur solely from some nervous affection, and may even be the first manifestation of an organic nervous disease. No one, according to Dr. Goldenberg, has yet succeeded in inducing extra-systoles by irritation of the heart nerves. The arrhythmia in tuberculous meningitis is of the infantile type—that is, it seems to be due exclusively to diastoles of various length. He maintains that heart murmurs may also be observed without organic lesions. Lüthje found systolic murmurs in 623 out of 857 children examined, but only 2 per cent. of the total number had certain signs of valvular disease. Beyer detected a systolic murmur in 352 out of 830 school children examined (more frequently in girls). In 253 cases the murmur was audible during repose; in the others, only after gymnastic exercises, and only in 14 cases were concomitant signs of a heart defect to be detected. Dr. Goldenberg explains these accidental murmurs as due merely to certain physiological and anatomical peculiarities of the circulation in children, differing possibly in various cases, such as more rapid flow of blood in the anæmic, or a slight and transient muscular mitral insufficiency.

Colony for Sane Epileptics.

The city council of Czernovitz has received the report of a deputation appointed to visit foreign, and particularly English, colonies for sane epileptics, in view of the projected colony to be started by the Bukovina province, of which Czernovitz is the capital. The deputation recommended as the most economical plan that the accommodation should be of the colony type, with villas to hold 15 to 20 patients. Central administrative buildings would also be required, as the colony would admit patients from the whole of Roumania, and the deputation recommended the erection of large workshops, so that continuous employment might be provided in bad weather when the patients could not be employed out of doors at farm and garden work. It is considered that constant work is the best thing for warding off attacks and conducing to a contented and peaceful state of mind. Though many epileptics are bad workers, the report states that proper personal supervision of their individual wants gives better working results. It is estimated that the number of epileptics for whom accommodation would be required is about 200.

The "Single-Child" System in Transylvania.

The Child Study Society of Transylvania has collected much data relating to the "single-child" system, which prevails chiefly in the Banat (the south-western part of Transylvania); their report states that until recently it had been thought that the system was thought to be purely a question of economics. People did not wish to distribute their lands and wealth between several children, but the custom had now become independent of land questions. It was quite clear that the "single-child" family did become not richer but poorer. The "single-child" generation tended to grow up idle and self-indulgent. If they were landed proprietors their farms were worked by others, necessitating payment of heavy wages. Farmers began to understand that the single-child system meant their ruin, but the custom was deeply rooted and the people were very conservative. People who had several children were actually despised. Another reason for the single-child system was feminine vanity; women thought that by avoiding childbirth they would remain young and enjoy life for a longer time. The spread of the system was aided by midwives and quacks, and, unfortunately, by doctors also; it was further promoted by unprincipled dealers in preventives, and by offensive advertisements in the press. The only child was spoilt by his parents, and too often entered early into a career of dissipation, the result being rapid physical and mental deterioration. The report points out that such a system must ultimately ruin the whole people.

Bucharest, June 9th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Medical Strike.

ON the last day of May occurred an incident which a short time ago would have seemed impossible. All doctors in Vienna and Lower Austria, numbering about 4800 (out of 6600 in the whole Austrian Republic), declared a strike lasting from 10 A.M. to 4 P.M. as a demonstration against the attitude of the Government, which is regarded as injurious to the interests of the profession. It was pointed out in a previous letter (THE LANCET, May 14th, p. 1043) that serious dissatisfaction prevailed in medical circles in regard to the recent acts of legislation, and that the relations between the profession as a whole and the authorities of the State were very strained. The new "Dentists Act," which gives to non-medical men the permission to do medical, or rather surgical, work on patients, finally brought the problem to a crisis. The Medical Council, together with the Economic Organisation, at once arranged for a demonstration which should indicate that the patience of the profession had been overtaxed. In spite of adverse criticism, especially amongst physicians of the older type, it was decided to stop all kind of medical work. A strike was ordered, and all private doctors, as well as the men working in the hospitals and charitable institutions in the city and district named, obeyed the order. Care was, of course, taken that pressing cases were not left without help, but on that day all other kind of medical work was brought to a standstill during the time mentioned above. At the same time a mass meeting of all the doctors on strike was convened, and the presidents of the medical representative bodies were able to point out, amidst a scene of enthusiasm, that for the first time in the history of the profession in Austria it had become possible to unite all medical men without exception against interference with their vital interests. The meeting carried unanimously resolutions, of which the following are abstracts:—

1. The medical profession protests most energetically against the present attitude of the authorities and legislative bodies in all problems of hygiene and public health. It demands that the medical corporations be acquainted with all measures of an economical or political nature affecting the interests of the profession before such measures are settled by Parliament, and expects the same treatment in this respect as that at present enjoyed by members of other callings.

2. A supreme health council shall be created, on which representatives of the profession are to hold a consulting interest, and this must be constructed in such a way that the majority of the members are practitioners and scientists holding a medical degree.

3. The present method of sickness insurance shall be replaced by a modern organisation ensuring a maximum of benefit both to the insured population and to the doctors working under the scheme; the economic interests of both parties to be cared for by a committee working under direct control of the Ministry responsible for social administration.

4. The profession demands an independent Ministry of Public Health, whose head shall be a doctor of medicine, and must be on equal footing with the other Ministers.

5. A new Health Act shall be brought at once before the legislative bodies; in order to begin with real sanitation of the country, the latest achievements of hygiene and public health must be embodied in it, and every law must, before passing the National Assembly, be referred to the Supreme Council of Health. The responsibility of all State officials for damage to individual health caused by their action or decision should be stated in this Act. Furthermore, the Act should expressly state that only duly qualified persons are permitted to practise on the human body and treat it in conditions of disease, such permission being subsequent to at least two years' service in a hospital.

6. Old age and sickness insurance shall be made compulsory for all practitioners; a reform of the medical curriculum, combined with post-graduate lectures free of charge, but compulsory after a lapse of years, are earnestly demanded.

The profession also desires convincing proof of compliance on the part of the Government with the demands framed in these six points. Medical men have often and too long been put off by promises, and they have now made up their minds to see their demands fulfilled. Unless the Government binds itself within four weeks to acknowledge the necessity of meeting these points, the entire profession will take up the fight and, if forced to do so, will stop all medical work. It is with the utmost reluctance that the leaders of the medical organisations have recommended such a step, but in this country it seems that only drastic measures can produce an effect on the mentality of members of the Government.

Proposed Health Certificate for Marriage.

The Vienna Board of Health has taken an important step in the direction of promoting control of public health by instituting three committees, each consisting of three fully qualified scientists, to draw up definite suggestions as to the issue of a health certificate to all parties intending to marry. The chief instigator of the procedure is Prof. Tandler, the former Under-Secretary of State for Health, and now head of the Office of Health in Vienna. He asserts that there are three groups of diseases which he intends to combat: sexual diseases, tuberculosis, and degenerative diseases in persons of tainted family. Every person must produce before marriage a certificate showing that he or she is not prone to one of the above-mentioned group, and the examination should be conducted in a thorough, but humane way. Professional secrecy would, of course, be guarded in a most strict manner, but the other party to the engagement would, naturally, be entitled to obtain full knowledge of the reasons for refusal of the permit to marry. Prof. Tandler believes that the setting up of committees will prompt many negligent patients to apply for treatment, and approach very nearly to the ideal condition of compulsion in respect of sexual disease. Refusal of a marriage permit could be withdrawn after appropriate treatment had been administered. The right of the community to control the health of its members is unquestionable, since it is entitled to send them to death on the battlefield. At present the number of persons suffering from tuberculosis is increasing steadily, and the morbidity from syphilis and gonorrhœa is alarmingly high, especially in the towns; indifference to the fate of the coming generation is therefore nothing less than a crime. The proposed "celibacy of the diseased" must not, of course, be restricted to poor people only, for it is just the wealthier classes of the population who could evade such a disagreeable condition of legislation, unless due precaution be taken. As is to be seen from these leading points, the main idea behind the suggestion of a health certificate for those about to marry is control of the health of children. Such a certificate would naturally only interfere with the legitimate descendants; illegitimate children could not be protected by it. But partial prophylaxis is better than none at all.

June 10th.

THE LATE DR. CHARLES E. CAMPBELL-HORSFALL.—The death is announced of Dr. Charles Campbell-Horsfall at Newquay. Dr. Campbell-Horsfall was the youngest son of the late Dr. Henry Horsfal; born at Masham, Yorkshire, in 1877, he was educated at Christ's Hospital, Trinity College, Harrogate, Yorkshire College, and Victoria University, becoming house physician at Leeds Infirmary, and house surgeon of Leeds Women's and Children's Hospital in 1899. He married, in 1901, Lilias Marianne, daughter of the late Robert Hume Campbell, of Glenclarnel. In 1901 he settled at Clevedon, Somerset, where his good work was such that when he resolved to leave the neighbourhood and seek a wider sphere a very largely signed petition was presented to him by the residents requesting him to reconsider his decision. He then entered practice at Newquay, where he secured a wide circle of friends and patients by kindness and ability. He sought recreation in field sports, with the whole-heartedness that characterised the discharge of his professional duties, and it was beside a moorland trout stream that he contracted the chill which finally proved fatal.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Hospitals.

THE report of the Board of Superintendence of the Dublin hospitals reveals their serious financial position. Only one of these institutions, the Westmorland Lock Hospital, has in the past year been able to keep its expenditure within its income. All the others, in spite of every economy in management, are weighed down by overdrafts. The report makes clear once again that the hospitals cannot continue to exist unless some new source of revenue is found. On the same day that the report of the Board was made public it was also announced that the Irish hospitals were not to share in the grant of half a million which the Government has promised to provide to meet urgent necessities. The omission with be felt in Ireland, where the hospitals owe their financial difficulties to the abnormal economic conditions of the past few years, just as much as the institutions in other parts of the kingdom do. These economic conditions have pressed especially hardly on Dublin, for business people and manufacturers in Ireland, outside Belfast did not share in the various war industries. Moreover, no part of the kingdom contributed so much to Red Cross Funds, in proportion to its wealth, as Ireland, and in none, therefore, did the hospitals suffer more from competition with claims for Red Cross purposes. On the other hand, the hospitality of the Irish hospitals to sick and wounded soldiers was given and accepted as freely as that of the hospitals elsewhere. It is not to be expected that those interested in the health of Ireland will assent calmly to the exclusion proposed by the Minister of Health.

Dublin Milk.

The Local Government Board has just issued a report on the milk of Dublin, based on investigations conducted by the bacteriologist to the Board, Dr. J. W. Bigger. He describes a serious state of affairs. Of the specimens of milk examined, taken at random from the milk sold in the city, no less than 8 per cent. contained tubercle bacilli. Dr. Bigger comments on the dirty condition of much of the milk, and states that those who supply and sell dirty milk to the children of Dublin are responsible for the deaths of hundreds each year. As a matter of fact, if the regulations in force in New York were applied in Dublin, 77 per cent. of the milk now being sold in Dublin would be condemned as being unfit for human food. Dr. Bigger urges that those who sell dirty milk should be fined, imprisoned, or prohibited from selling milk. At present, offenders who are convicted of diluting or skimming milk are usually treated with the utmost leniency, while prosecutions are not brought for selling dirty milk.

Sir Stewart Woodhouse, M.D. Dub., F.R.C.P. Irel.

To the great regret of a large circle of friends, the death has been learnt of Sir Stewart Woodhouse at the age of 75. Educated at Trinity College, Dublin, where he had a distinguished course in arts, obtaining high honours in both classics and philosophy, Stewart Woodhouse proceeded to medicine, graduating in 1872. Two years later he became a Fellow of the Royal College of Surgeons in Ireland, though he resigned this degree on becoming a Fellow of the Royal College of Physicians. In his early professional days he was lecturer in pathology in the Carmichael School of Medicine, and assistant physician to the House of Industry Hospitals, while he was engaged in practice as a physician. He resigned these appointments and abandoned his practice in 1880 to become a medical inspector of the Local Government Board. Ten years later he was appointed medical member of the General Prisons Board, and some 15 years ago he received the honour of knighthood. During his whole career as a public servant he maintained a high standard of duty, while showing kindness and consideration to his subordinates. In private life he was an unassuming and attractive companion and a man of wide reading.

Sir John Walton Browne, D.L.

At the investiture held by His Majesty the King during his recent visit to Belfast the honour of knighthood was conferred upon Dr. John Walton Browne, D.L. He is one of the oldest and most popular members of the medical profession in Ulster, and has given valuable services in many capacities. He is consulting surgeon to the Royal Victoria Hospital, and surgeon to the Belfast Ophthalmic Hospital. His new honour has given much satisfaction to his many friends both in the profession and among the general public.

Dr. S. B. Boyd Campbell has been elected assistant physician to the Royal Victoria Hospital, Belfast, in succession to Dr. J. E. MacIlwaine, who has become staff physician.

Colonel Professor Thomas Sinclair, C.B., F.R.C.S., has been elected a member of the Senate of the Parliament of Northern Ireland.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE eightieth annual meeting of this Association will be held from July 11th to 15th, under the presidency of Dr. C. Hubert Bond, in the Barnes Hall of the Royal Society of Medicine, Wimpole-street, London, W. On June 11th meetings of the Educational and Parliamentary Committees will be held. On July 12th, at 10.30 A.M., the meeting will proceed to elect officers of the Association for the year 1921–22, and reports of the council, officers, and standing committees will be read. The nominee for the Third Maudsley Lecture will be Sir Maurice Craig. At 11.30 A.M. a paper will be read by Dr. P. W. Bedford, entitled "The Goldsol Test in Mental Disease." At 3 P.M. Dr. C. H. Bond will deliver his presidential address on the Position of Psychological Medicine in the Medical and Allied Services. At 4.30 P.M. Dr. Edwin Goodall will give a demonstration of X Ray Photography of Barium Meals in cases of Dementia Præcox; and, jointly with Dr. H. A. Scholberg, a note on the Diastase-Contents of the Urine in 120 Cases of Mental Disorder. On July 13th, at 10 A.M., the following papers will be read: The Oxford Clinic, by Dr. T. S. Good; Psychological Medicine in Relation to Industry, by Dr. C. S. Myers, F.R.S.; and the Problem of Prevention in the War Psychoses, by Dr. Bernard Hart. At 2.30 P.M. the following papers will be read: Legislative Restrictions in Connexion with the Treatment of Incipient Insanity, by Dr. Wilfred Caroleu, secretary of the Royal Academy of Medicine, Barcelona; Mental Defect and the School Medical Service, by Dr. George A. Auden; Expatiation Mechanism in a Case of Schizophrenia, by Dr. Henry Devine. On July 14th, at 10 A.M., Dr. W. Ford Robertson will read a paper on Chronic Bacterial Infections in Dementia Præcox, to be followed by a communication on Change of Phase in the Psychoses, by Dr. Thomas Beaton, and one on Recurrent Phantasies of Infancy and Childhood as a Source of Delusions, by Dr. Edward Mapother. At 3 P.M. the members will assemble at the Springfield Mental Hospital, Tooting, London, S.W., where a paper will be read by Dr. Henri Colin, of Paris, entitled "Mental Hygiene and Prophylaxy." At 4 P.M. the subcommittee of the Springfield Mental Hospital kindly invite members of the Association and friends to a garden party to be held in the grounds of the hospital. On July 15th, at 10 A.M., at the Royal Society of Medicine, Dr. J. T. Dunstan will speak on the Feeble-minded Problem in South Africa and Dr. William Brown on Psychology and Psychotherapy. In the afternoon members and friends are invited by the London Asylums Mental Deficiency Committee to visit the mental hospitals on their estate at Epsom. The annual dinner of the Association will be held at the Connaught Rooms, Great Queen-street, London, W.C., on Wednesday, July 13th, at 7.30 P.M. Members desiring to attend are asked to send 30*s.* (the inclusive cost) as early as possible to the general secretary (Dr. R. Worth), Springfield Mental Hospital, near Tooting, London, S.W. 17.

THE third annual meeting of the Mental Hospitals Association will be held in the Guildhall, E.C., to-day, Friday, July 1st, at 11.30 A.M.

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton.

IN the annual report for 1920 of the medical officer of health for Brighton (Dr. D. Forbes) the estimated population is given as 137,685. The net births were 3087, the highest recorded number since 1884, giving a birth-rate of 22·28. The death-rate was 12·42 and the infant mortality-rate 67, both being the lowest ever recorded. There were 141 deaths from pulmonary tubercle, giving a death-rate of 1·1 per 1000. Of the 306 new cases of pulmonary tubercle notified, 69 were imported cases. The number of new houses erected during the years 1914, 1915, 1916, 1917, 1918, 1919, and 1920 were 44, 22, 9, 1, 5, 0, and 30 respectively. Of the 30 new houses erected in 1920, 14 were built by the corporation. In addition to the public abattoir there are 18 private slaughter-houses. "It would be of great benefit to the town if all the private slaughter-houses were abolished." The slaughtering for Hove is done in Brighton. Of 303 samples of wholesale milks 5 per cent. were non-genuine and of 105 samples of retail milks 10 per cent. were non-genuine. The average milk fat in the wholesale samples was 3·41 per cent. and in the retail samples 3·42 per cent. Of 19 samples of "pure cream" purchased under the Milk and Cream Regulations, five were found to contain preservatives. Dr. Forbes recommends that the State should supply vaccines and sera, in order that there may be a guarantee as to potency and reliability. The hospital records as to "return" cases of scarlet fever are given for 11 years and show that the percentage of discharges followed by return cases after one month, three months, and a year are 2·4, 3·1, and 3·7 respectively. "It is a good rule to exclude discharged patients from school for a period of four weeks." "The most important dangerous conditions are sores about the nose and nasal discharge. No notice need be taken of desquamation, red throats, enlarged tonsils, or moist noses without actual discharge." Since 1910 the removal of bedding for steam disinfection after scarlet fever and diphtheria has been given up. Bedclothes and personal clothing are washed at home. The rooms are sprayed with formalin. Mattresses, bolsters, and palliasses are not disinfected. The change has apparently done no harm, and Dr. Forbes thinks the disinfection of bedding after these diseases as usually carried out is "useless and a waste of public money." The corporation pay £300 a year to the Queen's Nurses for the home nursing of consumptives, and the nurses receive tuition from the tuberculosis officer. "One of the most pressing wants of the consumptive is the provision of light work which he can take up or drop as his condition allows. Few employers could afford to engage men on such conditions, and it would seem necessarily to fall to the local authorities to provide open-air workshops with canteens and club rooms for consumptives. The advantages are too obvious to require enumeration." Lectures have been arranged for the parents of school children on sex hygiene, afternoon lectures for mothers, and evening lectures for fathers, and were well attended. 671 new cases of venereal disease were treated at the V.D. clinic at the Royal Sussex County Hospital during the year. The 21 midwives in private practice sent for medical help in 173 cases, and £171 9s. was paid by the corporation to doctors called in in respect of 90 cases. Ante-natal work is chiefly done at the West-street Lying-in Hospital. Private midwives are invited to send patients, but very few avail themselves of the assistance offered. The work of the dental clinic for mothers and children makes slow progress. Thirty-one mothers and nine children had treatment during 1920. The number of ophthalmia as a public servant he maintained a high standard of duty, while showing kindness and consideration to his subordinates. In private life he was an unassuming and attractive companion and a man of wide reading.

Sir John Walton Browne, D.L.

At the investiture held by His Majesty the King during his recent visit to Belfast the honour of knighthood was conferred upon Dr. John Walton Browne, D.L. He is one of the oldest and most popular members of the medical profession in Ulster, and has given valuable services in many capacities. The average milk fat in the wholesale samples was 3·41 per cent. and in the retail samples 3·42 per cent. Of 19 samples of "pure cream" purchased under the Milk and Cream Regulations, five were found to contain preservatives. Dr. Forbes recommends that the State should supply vaccines and sera, in order that there may be a guarantee as to potency and reliability. The hospital records as to "return" cases of scarlet fever are given for 11 years and show that the percentage of discharges followed by return cases after one month, three months, and a year are 2·4, 3·1, and 3·7 respectively. "It is a good rule to exclude discharged patients from school for a period of four weeks." "The most important dangerous conditions are sores about the nose and nasal discharge. No notice need be taken of desquamation, red throats, enlarged tonsils, or moist noses without actual discharge." Since 1910 the removal of bedding for steam disinfection after scarlet fever and diphtheria has been given up. Bedclothes and personal clothing are washed at home. The rooms are sprayed with formalin. Mattresses, bolsters, and palliasses are not disinfected. The change has apparently done no harm, and Dr. Forbes thinks the disinfection of bedding after these diseases as usually carried out is "useless and a waste of public money." The corporation pay £300 a year to the Queen's Nurses for the home nursing of consumptives, and the nurses receive tuition from the tuberculosis officer. "One of the most pressing wants of the consumptive is the provision of light work which he can take up or drop as his condition allows. Few employers could afford to engage men on such conditions, and it would seem necessarily to fall to the local authorities to provide open-air workshops with canteens and club rooms for consumptives. The advantages are too obvious to require enumeration." Lectures have been arranged for the parents of school children on sex hygiene, afternoon lectures for mothers, and evening lectures for fathers, and were well attended. 671 new cases of venereal disease were treated at the V.D. clinic at the Royal Sussex County Hospital during the year. The 21 midwives in private practice sent for medical help in 173 cases, and £171 9*s*. was paid by the corporation to doctors called in in respect of 90 cases. Ante-natal work is chiefly done at the West-street Lying-in Hospital. Private midwives are invited to send patients, but very few avail themselves of the assistance offered. The work of the dental clinic for mothers and children makes slow progress. Thirty-one mothers and nine children had treatment during 1920. The number of ophthalmia

VITAL STATISTICS OF LONDON DURING MAY, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 9·6 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 10·2, 9·7, and 8·7 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Fulham, Chelsea, the City of Westminster, St. Pancras, Lambeth, and Lewisham; and the highest in Hammersmith, Stoke Newington, Hackney, Shoreditch, Bethnal Green, and Stepney. The prevalence of enteric fever was somewhat greater than in the preceding month; of the 23 cases notified during the four weeks ended May 28th, 3 cases belonged to each of the boroughs of Stepney, Wandsworth, and Woolwich, and 2 each to St. Pancras, Hackney, and Poplar. There were 18 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 9, 10, and 10 at the end of the three preceding months; the weekly admissions averaged 5, against 2, 3, and 2 in the three preceding months. The prevalence of scarlet fever was 20 per cent. greater than in the preceding month; this disease was proportionally most prevalent in Hammersmith, Stoke Newington, Hackney, the City of London, Bethnal Green, and Stepney. The Metropolitan Asylums Hospitals contained 3375 scarlet fever patients at the end of the month, against 3709, 3187, and 3217 at the end of the three preceding months; the weekly admissions averaged 507, against 401, 409, and 411 in the three preceding months. The prevalence of diphtheria was somewhat less than in April, and was lower than in any preceding month since August of last year; the greatest proportional prevalence of this disease was recorded in Hampstead, Hackney, Holborn, Finsbury, Shoreditch, and Bethnal Green. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2700, 2652, and 2129 at the end of the three preceding months, numbered 2121 at the end of May; the weekly admissions averaged 241, against 333, 290, and 261 in the three preceding months. Erysipelas was proportionally most prevalent in Kensington, St. Marylebone, Shoreditch, Southwark, Deptford, and Greenwich. Eighteen cases of encephalitis lethargica were notified during the month, against 77, 56, 24, and 14 in the four preceding months; of these, 3 belonged to Stepney, 3 to Camberwell, 2 to Hammersmith, and 2 to Wandsworth. The cases of cerebro-spinal fever numbered 11, against 17, 14, and 12 in the three preceding months; of these, 4 were notified from Wandsworth, 2 from Poplar, and 2 from Lambeth. The 32 cases of puerperal fever included 7 in Islington and 4 in Hackney. The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended May 28th the deaths of 3879 London residents were registered, equal to an annual rate of 11·2 per 1000; in the three preceding months the rates had been 14·0, 13·6, and 12·6 per 1000. The death-rates ranged from 8·2 in Lewisham, 9·2 in Holborn, 9·5 in Hampstead, 9·8 in Woolwich, 10·0 in Deptford, and 10·1 in Bermondsey, to 12·8 in St. Marylebone, 13·0 in Finsbury, 13·2 in Kensington and in Chelsea, 13·5 in the City of London, and 15·2 in Shoreditch. The 3879 deaths from all causes included 213 which were referred to the principal infectious diseases; of these one resulted from enteric fever, 16 from measles, 22 from scarlet fever, 46 from whooping-cough, 77 from diphtheria, and 51 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Chelsea or in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in the City of Westminster, St. Marylebone, Stoke Newington, Holborn, Southwark, Lambeth, and Greenwich; and the highest in Paddington, Hampstead, Finsbury, Shoreditch, Stepney, and Deptford. The fatal case of enteric fever belonged to Wandsworth; the average number of deaths from this disease in the corresponding period of the five preceding years was 5. The 16 deaths from measles were less than one-eighth of the

* Including membranous croup.

neonatorum cases notified was 29. Four of the most severe cases were treated in the sanatorium. "Ulceration of the cornea occurred in one case only, this cleared up completely under treatment." The following scheme of precautions has been drawn up for the use of the midwives:—

1. Directly the head of the infant is born wipe each eye with clean cotton-wool. Use a fresh piece for each eye; burn it after use.

2. As soon as the child is separated, wash the child's eyelids with a warm boracic lotion.

3. When first bathing the child use fresh water and a clean towel for the face and allow no bath water to enter the eyes. After the bath open each eye and thoroughly wash out with a warm boracic lotion—a thorough irrigation. This is most important.

4. Then open the eyes again and drop into each eye one drop of argyrol (10 per cent. strength). Drops of argyrol must on no account be continued after the first day except they are ordered by a doctor.

5. Continue ablution as stated in (3) daily during attendance.

6. At no time during the lying-in period use the mother's sponges, napkins, towels, &c., for the child.

A ward at the sanatorium is set aside for infants suffering from malnutrition, mostly for those attending the infant welfare centres who fail to improve. Dr. Forbes's report gives full particulars of the work of the school medical department. He draws attention to the increasing interest of the parents in this work, and expresses his warm appreciation of the helpful and enthusiastic assistance given by the teachers.

Huddersfield.

The annual report for 1919 of the medical officer of health for Huddersfield consists of the usual tables and a short introductory letter, in which Dr. S. G. Moore tells us that "in accordance with instructions it (the report) contains essential facts only." The Registrar-General's estimate of the population is, for birth-rate 118,036 and for death-rate 105,346. Dr. Moore is of opinion that the establishment of "British Dyes" has caused exceptional immigration and that the population was over 120,000. Even if he is correct, the error in the rates would not be a very great one. The death-rate for 1919 was 15·81 and the infant mortality rate 95. The birth-rate was only 12·66 and for the second year in succession there have been more deaths than births in Huddersfield. In 1918 the births were 1575 and the deaths 1737, and in 1919 the births numbered 1519 and the deaths 1701. No wonder Dr. Moore writes: "The least satisfactory feature of the vital statistics of the borough is presented by the birth-rate." During the influenza year (1918) half the 45 largest towns had death-rates higher than their birth-rates, but during 1919 the only towns which kept Huddersfield company in this respect were textile mill towns—namely, Blackburn, Bradford, Halifax, and Oldham. At the end of 1919 came the revival of the birth-rate, and in 1920 none of the 45 towns had a death-rate higher than the birth-rate. in Huddersfield the death-rate being about 13·0 in comparison with a birth-rate of about 18·0. Dr. Moore records that the system of voluntary notification of pregnancy, begun in 1916, "continues to confer benefits upon paido-poietics, both substantial in character and to a considerable extent. .... The work proceeds smoothly and agreeably to all concerned." During 1919 34 per cent. of the pregnancies were notified. We must enter a gentle protest against the introduction of the dreadful word "paido-poietics" to denote the expectant mother. It may be a little illogical to call a woman pregnant for the first time a "mother," even when qualified by the epithet "expectant," but the Greeks used Dr. Moore's term equally of begetting and conception.

Barnstaple.

In the health report for 1920 of the borough of rnstaple the estimated population is given as 14,270. There were 364 births in 1920 and 238 in 1919. The death-rate in 1920 was 13·7 and the infant mortality rate 43·9. Dr. H. C. Jonas submits a very complete report of the work of the health and school medical departments. The main industries of the town are lace manufacture, cabinet-making, gloving, agriculture, and (recently) shipbuilding. The tuberculosis death-rate appears high, 2·3 for 1920 and 1·6 for 1919. Among the matters reported as needing attention are the substitution of "proper covered ashbins for the filthy boxes which are still far too common," and the provision of public baths and school baths. Satisfactory arrangements have been made for the treatment of the school children. A school dentist began work in April and is "pleased with the results so far obtained," but reports some reluctance to accept treatment both in the school work and at the maternity clinic. The school nurse also acts as health visitor and thus overlapping is avoided. Of three schools reported in 1919 as unsatisfactory, two have been renovated and the worst has been closed, army huts having been put up to provide the necessary accommodation. Dr. Jonas reports that the converted army huts make good and airy class-rooms. Progress with the council's housing scheme has been slow. The sites for 200 houses have been bought and laid out. In the meantime an unhealthy area including 40 houses cannot be dealt with. There is also great difficulty in getting repairs done so as to keep existing houses fit for habitation. The owners say they cannot do the repairs, and owing to the shortage the council does not want any houses closed. This would seem to be a case where the local authority should do the repairs and recover the cost from the owners.

SCHOOL MEDICAL SERVICE.

Rutland County Council.—In his annual report for 1920 Dr. C. Rolleston complains of the want of coöperation between the public health and education authorities, and that "within no distant period there will be two sets of officials visiting each home in the county, one on account of infant welfare, the other for the well-being of the school child." Nursing assistance is needed both for the ophthalmic surgeon and the dentist. The total number of entrants, intermediates, and leavers examined during the year was 731. Parents attended 84 per cent. of the examinations. There is a good deal of parents' opposition to the treatment of teeth and of tonsil and adenoids. The percentage of clean children wa 84·9, of normally nourished children was 94, and 10 of the 731 examined were found to be in urgen need of dental treatment. During 14 months th school dentist inspected 1515 children, of whom 1303 (85 per cent.) were referred for treatment an 912 (69·9 per cent.) actually treated. Dr. Rolleston does not think the amount of dental caries is wors in Rutland than elsewhere, and instances Hull childre with 85 per cent. and Sunderland with 94·5 per cent. o caries. He also compares the 70 per cent. acceptin treatment with the 48 per cent. of Leeds and the 49 pe cent. of Stoke-on-Trent. The parent of a child with 11 carious teeth wrote to the school dentist, "He car eat and drink more than enough, and that's all I want him to do." And another parent, "I am not going to have him messed about just to please you." The arrangements for treating tousils and adenoids are not satisfactory, and Dr. Rolleston recommends his committee to come to an agreement with Oakham Cottage Hospital and Stamford Infirmary. Dr. Rolleston records the gradual extinction of ringworm in Rultand "which has been brought about by the application of X rays to all cases irrespective of the extent of the disease." Under the heading "Sanitary Conditions," Dr. Rolleston comments on dirty towels and lavatories, the unsatisfactory water-supply of the majority of the schools and the continued existence of "privy vaults," and puts in a plea for more playground classes.

VITAL STATISTICS OF LONDON DURING MAY, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 9·6 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 10·2, 9·7, and 8·7 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Fulham, Chelsea, the City of Westminster, St. Pancras, Lambeth, and Lewisham; and the highest in Hammersmith, Stoke Newington, Hackney, Shoreditch, Bethnal Green, and Stepney. The prevalence of enteric fever was somewhat greater than in the preceding month; of the 23 cases notified during the four weeks ended May 28th, 3 cases belonged to each of the boroughs of Stepney, Wandsworth, and Woolwich, and 2 each to St. Pancras, Hackney, and Poplar. There were 18 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 9, 10, and 10 at the end of the three preceding months; the weekly admissions averaged 5, against 2, 3, and 2 in the three preceding months. The prevalence of scarlet fever was 20 per cent. greater than in the preceding month; this disease was proportionally most prevalent in Hammersmith, Stoke Newington, Hackney, the City of London, Bethnal Green, and Stepney. The Metropolitan Asylums Hospitals contained 3375 scarlet fever patients at the end of the month, against 3700, 3187, and 3217 at the end of the three preceding months; the weekly admissions averaged 507, against 404, 409, and 411 in the three preceding months. The prevalence of diphtheria was somewhat less than in April, and was lower than in any preceding month since August of last year; the greatest proportional prevalence of this disease was recorded in Hampstead, Hackney, Holborn, Finsbury, Shoreditch, and Bethnal Green. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2706, 2652, and 2420 at the end of the three preceding months, numbered 2121 at the end of May: the weekly admissions averaged 241, against 333, 290, and 261 in the three preceding months. Erysipelas was proportionally most prevalent in Kensington, St. Marylebone, Shoreditch, Southwark, Deptford, and Greenwich. Eighteen cases of encephalitis lethargica were notified during the month, against 77, 56, 24, and 14 in the four preceding months: of these, 3 belonged to Stepney, 3 to Camberwell, 2 to Hammersmith, and 2 to Wandsworth. The cases of cerebro-spinal fever numbered 11, against 17, 14, and 12 in the three preceding months; of these, 4 were notified from Wandsworth, 2 from Poplar, and 2 from Lambeth. The 32 cases of puerperal fever included 7 in Islington and 4 in Hackney. The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended May 28th the deaths of 3879 London residents were registered, equal to an annual rate of 11·2 per 1000; in the three preceding months the rates had been 11·0, 13·0, and 12·6 per 1000. The death-rates ranged from 8·2 in Lewisham, 9·2 in Holborn, 9·5 in Hampstead, 9·8 in Woolwich, 10·0 in Deptford, and 10·1 in Bermondsey, to 12·8 in St. Marylebone, 13·0 in Finsbury, 13·2 in Kensington and in Chelsea, 13·5 in the City of London, and 15·2 in Shoreditch. The 3879 deaths from all causes included 213 which were referred to the principal infectious diseases; of these one resulted from enteric fever, 16 from measles, 22 from scarlet fever, 46 from whooping-cough, 77 from diphtheria, and 51 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Chelsea or in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in the City of Westminster, St. Marylebone, Stoke Newington, Holborn, Southwark, Lambeth, and Greenwich; and the highest in Paddington, Hampstead, Finsbury, Shoreditch, Stepney, and Deptford. The fatal case of enteric fever belonged to Wandsworth; the average number of deaths from this disease in the corresponding period of the five preceding years was 5. The 16 deaths from measles were less than one-eighth of the

* Including membranous croup.

average; of these, 5 belonged to Shoreditch, 5 to Stepney, and 2 to Lambeth. The 22 fatal cases of scarlet fever exceeded the average by 13; of these, 3 belonged to Stepney, 3 to Wandsworth, and 2 each to Hammersmith, Fulham, Islington, and Woolwich. The 46 deaths from whooping-cough were about half the average number; this disease was proportionally most fatal in Fulham, Holborn, Battersea, Wandsworth, Deptford, and Woolwich. The 77 fatal cases of diphtheria were 33 in excess of the average; the greatest proportional mortality from this disease occurred in Hampstead, Finsbury, Shoreditch, Bethnal Green, and Deptford. The 51 deaths from infantile diarrhœa were 2 below the average; this disease was proportionally most fatal in Paddington, Kensington, Shoreditch, Stepney, and Camberwell. In conclusion, it may be stated that the aggregate mortality in London during May from these principal infectious diseases was 37 per cent. below the average in the corresponding period of the five preceding years.

The Services.

ARMY MEDICAL SERVICE.

Temp. Hon. Col. C. J. Bond relinquishes his commn. and retains the hon. rank of Col.

ROYAL ARMY MEDICAL CORPS.

Lt.-Cols. H. W. H. O'Reilly and C. A. Stone are placed on ret. pay.

Temp. Capts. J. P. Bonfield and C. F. Simpson relinquish their commns. and retain the rank of Capt.

ARMY DENTAL CORPS.

Temp. Capt. O. G. E. Simpson, Dental Surg., from Spec. List, to be Capt.

Temp. Capt. J. Morrey, Dental Surg., from Gen. List, to be Lt., with the temp. rank of Capt.

TERRITORIAL FORCE.

Maj. J. A. Paterson (late R.A.M.C.), to be Lt., and relinquishes the rank of Maj.

Maj. F. W. Johnson resigns his commn. and is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

Maj. C. H. Bullen resigns his commn. and retains the rank of Maj.

Capts. B. E. Potter and A. R. Muir to be Majs.

Capt. (actg. Maj.) R. Briercliffe relinquishes the actg. rank of Maj. on vacating the appt. of D.A.D.M.S.

Capt. A. U. Webster (late R.A.M.C.) to be Capt.

Capts. C. B. Johnstone and M. T. Ascough resign their commns. and are granted the rank of Maj.

Capt. J. Howard resigns his commn. and retains the rank of Capt.

HÆMOGLOBIN.

To the Editor of THE LANCET.

SIR,—The interesting leading article in your issue of June 25th on the subject of hæmoglobin omits any statement, except the most general, of the reasons why hæmoglobin is carried in corpuscles rather than in solution in the blood plasma, nor are these at all frequently discussed. It may not be out of place therefore to point out that a solution of hæmoglobin has properties in some respects very different from those of blood.

1. It is possible to obtain a solution of hæmoglobin which, bulk for bulk, contains as much of the pigment as does blood. Such a solution is, comparatively speaking, viscous and therefore could only be driven along a system of fine tubes such as the capillaries by the application of considerable force.

2. A concentrated solution of hæmoglobin, as compared with blood, only passes through filter paper with difficulty, yet by a curious paradox the molecules of which this solution is composed pass through a collodion membrane that would be quite impervious to corpuscles. Hence hæmoglobinuria consequent on laking of the blood.

3. Owing to the viscosity of the solution, any effort to make it pass along a tube merely achieves the displacement of the central core of fluid. The arrangement of the hæmoglobin in corpuscles, which are commensurate in size with the capillaries, ensure the forward movement of the whole contents of the capillary at approximately the same rate.

4. The properties of hæmoglobin as an oxygen carrier are extremely sensitive to properties of the solvent—e.g., its reaction, its partial pressure of CO_2, its potassium content, its temperature, &c. The segregation of the hæmoglobin in corpuscles allows its exposure to the conditions most advantageous for it without imposing such conditions on the body generally.

Without entering into any controversy as to the extent to which the red blood corpuscle may be regarded in itself a living organism, rather than a suitable casing for the sixty-millionth part of one gramme of hæmoglobin, the above facts are sufficient to illustrate the advantages which accrue to the organism by the trick of carrying large quantities of hæmoglobin which is packed inside special corpuscles.

I am, Sir, yours faithfully,

J. BARCROFT.

The Athenæum, Pall Mall, S.W., June 27th, 1921.

ON DEATH FROM RESPIRATORY AND NOT FROM CARDIAC FAILURE.

To the Editor of THE LANCET.

SIR,—A note in the public press on June 20th of a coroner's inquest on a case of sudden death in which the patient's heart continued to act for eight hours after respiration had ceased, reminds me of several instances of this nature, one of which occurred in my clinic at St. Bartholomew's, and three others under my surgical colleagues there. I published this series of cases in the *Edinburgh Medical Journal*, New Series, Vol. III., 1898, p. 145, and communicated them to the Section of Medicine at the International Congress at Moscow in 1897. In all these, and others that have been reported, the lesion in the brain has arisen from abscess, occipital injury, or tumour, and it appears to be certain that the respiratory centre is clearly more sensitive than its neighbour the cardiac centre, and is the first to yield under undue intracranial pressure.

I am, Sir, yours faithfully,

June 21st, 1921. DYCE DUCKWORTH.

SANATORIUM CONTROLS.

To the Editor of THE LANCET.

SIR,—As the various criticisms of Dr. E. Ward's original article on Controlled Sanatorium Results seem to have brought no light to him, and he reiterates his opinions in your issue of this date, further comment appears to be desirable to prevent the impression remaining in his mind that his presentation of the case against sanatorium treatment is unanswerable. Dr. Ward has correctly guessed that my comparison of other forms of treatment to sanatorium with moonlight to sunlight was picturesque and not mathematical, and was intended to arrest his attention, which it has done to the extent of leading him to look up the relative intensities of the rays from the two luminaries. It is fortunate that I did not employ the words "infinitely superior," or he would have been impelled to criticise the comparison in terms of Einstein's theory of relativity. With regard to expectation of life after sanatorium treatment, taking the Midhurst figures as a standard, if I were a patient under the views enunciated by Dr. Ward my expectation of life would be nil. It would require a complete number of your journal to fully criticise the original paper on "Sanatorium Controls," and in my former letter I merely instanced the case of a patient who remained for three years in an institution to secure a complete arrest of extensive disease, not to sum up the results of 20 years' sanatorium experience, but to endeavour to enlarge Dr. Ward's ideas of time in relation to treatment. He states in your last issue that he included in his results cases in which individuals remained only one month because "a line had to be drawn somewhere," but if so, why not draw it at one week; or, better still, why not follow the rule of some general hospitals which exclude from their statistics any deaths occurring within 48 hours of admission? What would be thought of a fire brigade which exercised its activities on a conflagration for one hour, then withdrew; and included the attempt among the published results of its efforts? The statement is made that three months is the standard period of sanatorium treatment in this country for working-class patients, and I should be interested to learn who fixed this standard, for I have never heard of it, and it certainly is not the standard in the West Riding of Yorkshire.

Twenty years ago I decided upon six months as a reasonable period to give a moderately early case an opportunity of securing arrest of the disease; but if Dr. Ward's "standard" is general, there need be little surprise if sanatorium treatment is condemned. Has it not occurred to him that a more prolonged period is the necessity and not improved methods; or is the "standard" so fixed in his mind that a method of treatment must be found which will prove effective in three months? From a careful study of a patient the experienced sanatorium physician should form his opinion of the duration of treatment likely to be necessary, and when collating his statistics could give under a separate heading the results in cases of individuals who left the institution prematurely.

Dr. Ward writes of the enormous expense of retaining patients in a sanatorium for an extended period of a year or two; but he is evidently unaware of the length of time it may be necessary to isolate patients: some may live five or six years in a hospital, and have done so to my knowledge, at an expense by no means inconsiderable. Some voices are now crying out that improved housing conditions are the desirable means for the 'cure" of tuberculosis; others that "prevention in the young" is the watchword; while the patient with declared pulmonary tuberculosis is to be ignored apparently, or left to die quietly—if he will—in an isolation hospital, as Dr. Ward implies by his words "the most hopeful means I can see of dealing with the tuberculosis problem is by adequate isolation of infective cases." He is consoled and supported in his poor opinion of sanatorium treatment "by the whole-hearted agreement of several practitioners of experience," but I have usually found that practitioners who did not speak favourably of it were those who were unable to diagnose the disease in its early stages. Recently a patient came under my care who had a severe initial attack of hæmoptysis two years before, and should have been sent to a sanatorium then; but her medical attendant shared Dr. Ward's opinion that home treatment was as good as, or better than, sanatorium; and she was naturally in an advanced condition of disease when allowed to visit a tuberculosis officer. She will be a considerable expense, unfortunately, as an inmate of a hospital for advanced cases now, whereas if Dr. Ward had no supporter for his views there might have been some likelihood of arresting the disease within 12 months at a much lower expense. Dr. Ward seems to consider the quotation of one case as though it comprised a statistical table, so I mention that I merely cite this as a pernicious example of what may be characterised as the logical outcome of his "teaching."

I am, Sir, yours faithfully,

THOMPSON CAMPBELL, M.D.,

Medical Superintendent, West Riding County Sanatorium, Ilkley.

June 25th, 1921.

THE VALUE OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—The arguments used concerning the value of sanatorium treatment are full of fallacies; and it is surprising that these have not been widely recognised. I will here refer to one only. A patient needing for recovery certain conditions of life, which he can sometimes get at home and can usually get at a sanatorium, is given these conditions at a sanatorium for three months when he needs 12, six months when he needs 24 or 36. The improvement, or the reverse, is rightly credited or debited to the institution. In the next stage of treatment, at home under more or less unfavourable conditions, he sometimes continues to improve but often relapses. Surely this part of the result should be credited or debited to the home conditions, not to the sanatorium. If not, then if a rheumatic patient after treatment at a spa or by salicylates subsequently relapses, the relapse should be debited to the previous treatment; but nobody dreams of doing so.—I am, Sir, yours faithfully,

F. R. WALTERS,

Joint Tuberculosis Officer to the Surrey County Council.

Farnham, June 22nd, 1921.

THE VALUE OF ENGLISH PHTHISIS SANATORIA.

To the Editor of THE LANCET.

SIR,—Dr. E. Ward, tuberculosis officer for South Devon, has done useful service in calling in question the value of some at least of our working-class phthisis sanatoria. His carefully written paper, read in Exeter last January, gives the following arresting figures for first stage cases amongst the poorer classes. (A) = sent to sanatoria; (B) = not sent to sanatoria:—

	(A) per cent.	(B) per cent.
After Two Years.		
Classes 1 and 2—i.e., cures and doubtful cures	64	88
Classes 4 and 5—i.e., "too ill to work" and "very ill"	21	3
Dead	6	1
After Four Years.		
Cures and doubtful cures	67	83
Too ill to work and very ill	11	6
Dead	11	3

His statements, thoughtfully safeguarded as they are, merit the most careful attention—the more so that no evidence to the contrary seems to be forthcoming. Dr. Ward tells us that most of the cases discharged from these sanatoria with "disease arrested" relapse within a short time; that to say that 20 per cent. of early cases are cured is probably to make an overstatement; that patients commonly lose ground on returning home more quickly than if they had remained at home; that those, of his series, who were longest in a sanatorium gave worse results than those who had been only a short time in one; and that no case which seems to be improving at home should be sent to a sanatorium.

Such an indictment, coming from a competent observer, calls imperatively for a pause in our public expenditure on phthisis sanatoria until the whole subject has been thoroughly investigated. Meanwhile there are some points which need to be considered.

1. Our sanatoria appear to be furnishing considerably worse results than might reasonably have been anticipated from the Nordrach experience. But Nordrach was singularly well placed and many of our sanatoria are remarkably badly placed. Abundant proof has been given of the importance of securing, especially in this country, sites well sheltered from the impact of strong, prevalent rain-bearing winds, yet practically no attention has been paid to this proof and until recently no serious attempt has been made to verify it. This inattention may be explained partly by the general inattention with which many members of the profession read their journals, partly by the great financial inconvenience of accepting the conclusion. The serious waste of public money on bad sites, now coming into view, may presently, however, make it even more inconvenient to ignore it. For there are certainly sanatoria which, from their faulty situation, may reasonably be regarded as death traps for their phthisical inmates, and such sanatoria should be scrapped forthwith.

2. I believe there are many cases for which the climates of this country are not so suitable as certain climates abroad, notably the climates of some high altitudes where windlessness is a feature—Davos for instance. Before the sanatorium boom began these climates were well recognised and highly valued by the medical profession.

3. Dealing with our poorer patients, for whom distant resorts are not available, we shall do well to remember Walther's view that sanatoria are useless for them, and Noy Scott's recently expressed opinion "that if much of the money, which has been spent on sanatoria, had been used to enforce by-laws regarding fresh air and sunlight in cottages we should have had better results."

4. In emphasising the results of sanatorium treatment and treatment outside, we shall, I am sure, become utterly confused unless we restrict ourselves to sanatoria in places sheltered from strong rain-bearing winds.

5. Lastly, we shall do well to make certain that all the "early cases cured" have been really tubercular; that some so classed have not been tubercular, I fancy most people are convinced.

I am, Sir, yours faithfully,

Exeter, June 25th, 1921. W. GORDON.

INTERNATIONAL SANATORIUM INSPECTION.

To the Editor of THE LANCET.

SIR,—Dr. E. Ward, in your issue of June 25th, repeats under the title "A Further Consideration of Sanatorium Controls," the valuable suggestion, made in your leading article of April 16th, that, in view of the unsatisfactory state of sanatorium treatment in this country, public sanatoriums should be inspected by a commission of experts who would investigate the conditions which at present make sanatorium treatment a byword and a reproach. With regard to the composition of such a commission I doubt whether Dr. Ward's trinity—a general practitioner, a surgeon, and an intelligent layman—would contribute more han a Gilbertian atmosphere to the proceedings; we all know the non-expert inspector as an amiable old woman of either sex, who ambles round an institution, seeking knowledge and finding "eyewash." But I agree with Dr. Ward in distrusting a body composed solely of medical superintendents in this country; the accountant who audits his own figures is apt to do so with his tongue in his cheek. It is unfortunate that, in the United Kingdom, the names of the persons familiar with the modern treatment of tuberculosis do not, as a rule, carry much weight; and the persons whose names do carry weight are, with a few exceptions, unfamiliar with the modern treatment of tuberculosis. When we compare the remarkable achievements of foreign sanatoriums, such as Vejlefjord and Loomis, with the disheartening records of our own sanatoriums, the question naturally arises: Could not the medical officers of foreign sanatoriums which have "delivered the goods" be induced to inspect and report on the public sanatoriums in this country? Of course, national pride would kick at such a notion. Last summer, when I met Prof. Saugman in London and he expressed a wish to visit a certain well-known sanatorium, national pride prompted me to divert him from his object, for I knew that this sanatorium was about 15 years behind the times in lung collapse treatment, in which Prof. Saugman is a pioneer. But we might, perhaps, circumvent our rather inconvenient national pride by making international inspection of sanatoriums reciprocal, and in sending our own medical superintendents to inspect and report on foreign sanatoriums, we should at once soothe their feelings and surreptitiously increase their knowledge and usefulness.

I am, Sir, yours faithfully,

CLAUDE LILLINGSTON.

Gorleston-on-Sea, June 25th, 1921.

RESULTS OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—At this sanatorium we have excellent opportunities for finding out what happens to our cases after discharge. We find the following to be true: (1) that no case practically makes a recovery which does not show marked improvement whilst in the sanatorium; (2) that cases early in time, that is to say, cases which have exhibited symptoms of activity for a short time before admission, usually progress to complete recovery. I have come to the conclusion that all cases which will get well outside the sanatorium will get well in the sanatorium; in addition, many cases that will get progressively worse when outside will recover in the sanatorium; that the only chance for most bad cases is to admit them to the sanatorium. I attribute the difference in results obtained here in respect of early cases mainly to the liberal amount of rest in bed these cases obtain, and to the regulation of the amount of rest required by means of a carefully registered rectal temperature. The duration of residence of these cases is usually five calendar months, though in the case of pleurisies this may be in some cases reduced to three months; if they are sent in at once, the same might apply to cases of hæmoptysis. To produce any real lasting results the patients should on discharge be able to do without after-care except in so far as they can exercise it themselves, and should as a rule be able to go on with their previous occupations.

To understand this subject properly it is necessary to take very careful histories of these cases, for by this means it becomes possible to discover the time when these patients should first have been treated. and much valuable information will be gained which may prevent mistakes being made in the future. Thus if a patient has suffered from pleurisy five years previously, and we find that he has during that time developed into a typical case of chronic pulmonary tuberculosis, we should admit if we omitted to treat him properly in a sanatorium that we have committed a gross blunder. Whether a patient should be treated in a sanatorium or not will of course depend on the presence or absence of fever, as indicated by the taking of a rectal temperature and the presence or absence of symptoms of active disease. Though the isolation of the advanced case should be encouraged where possible, it should be remembered that the treating of the early case is the proper way to eradicate the disease; for we must all surely admit that most cases which can be treated as advanced have been infectious often for long periods, and must during that time have infected a considerable number of people; furthermore, the prospect of segregation will cause many persons to hide their disabilities for as long as possible and thus cause spread of the disease.

In conclusion, I would urge that such sanatoriums as exist should be used for the purpose for which they were intended—that is, for the treatment of cases early in time and therefore for the most part curable, and that always the early case should be given the preference over the advanced; it should of course be remembered that if an early case be sent to a farm or the seaside for a few months before going to a sanatorium, at the expiration of that period it may be impossible to accomplish anything. In addition, it would be as well that when these patients do get admitted to a sanatorium they should be treated correctly. I may say that at a time when I had the admission of these cases in my own hands I had little difficulty in persuading patients to undergo treatment. Of the first 500 cases admitted to the Ayrshire Sanatorium who remained for five months 120 were in the first stage, and of these in 1921 77 per cent. were well; 182 were in the second stage, and of these 52 per cent. were alive, many at their previous occupations; and of 198 third stage cases only 17 per cent. were alive. The duration of time in these cases from their admission to when the calculation was made varying from July, 1906, to August, 1912, the calculation was made by Mr. Steven of Edinburgh in April, 1921. I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, June 25th, 1921.

CONCERNING THE ELECTRICAL ACTION OF THE HUMAN HEART.

To the Editor of THE LANCET.

SIR,—I greatly admire Prof. Bayliss's book entitled "Principles of General Physiology," and regard it as a valuable contribution to the advancement of physiological knowledge. It is the outcome of the matured thought of one of the leaders of the premier school of physiology in London and may be expected to serve for many years to come as a standard work of reference for many future workers and writers. The book presents an elaborate digest of modern physiological fact and doctrine, and forms a very convenient and accessible store-house of information. Not the least of its merits consists in the bibliographical accessories by which a very humanising quality is imparted to the text.

Uniform perfection of treatment over so extensive a field is hardly to be expected of any writer, however learned and industrious he may be, and as the author himself states in his preface "Important points have most probably escaped notice and I shall be very grateful to readers who will inform me of these omissions and also for criticism in general."

So I shall take the liberty of calling attention to an omission in the account of the electrical action of the human heart. In the section (third edition, pp. 656 et seq.) dealing with the electrical changes of the heart Prof. Bayliss gives an account of the subject that does not contain any allusion to my own discovery of the primary facts in 1887 which formed the point of departure for a long series of investigations by many physiologists and physicians. Nor does he include in his bibliography any one of the several papers on the subject published by me during the period 1887–89. Of these papers the first was published in the *Journal of Physiology*, Vol. VIII., p. 229, and the last and most complete in the Philosophical Transactions of the Royal Society, p. 169, 1889, under the title: "On the Electromotive Changes connected with the Beat of the Mammalian Heart, and of the Human Heart in particular." The subject was taken up and extended by Einthoven, whose first paper appeared in 1895 in *Pfluger's Archiv*, Vol. LX., p. 101, under the title "Ueber die Form des menschlichen Electrocardiogrammes." and the opening sentence of this paper contains a perfectly clear and frank acknowledgment, as is customary between men of science, which runs as follows: "Vor mehr als 6 Jahren bereicherte Augustus D. Waller, die Wissenschaft mit der Kenntniss des menschlichen Electrocardiogrammes. *Er zeigte, dass die rhythmischen* Schwankungen, welche der electrische Spannungsunterschied zwischen den verschiedenen Stellen des Korpers erfahrt, aus keine andere Weise als durch die electromotorischen Wirkungen des Herzmuskels verursacht werden."

I am, Sir, yours faithfully,

A. D. WALLER.

Physiological Laboratory, University of London,
South Kensington, June 18th, 1921.

To the Editor of THE LANCET.

SIR,—I am obliged to you for letting me see in advance a communication from Prof. A. D. Waller. I regret to have omitted to refer to the fact that Prof. Waller was the first to show that an electrical change associated with the beat of the human heart can be detected by leading off appropriate points on the surface of the skin to a sufficiently delicate recording instrument, and will endeavour to correct a new edition accordingly. I think, however, that it will be obvious that in a book dealing with general principles a detailed historical account would be out of place in the case in point. My object was to give as briefly as possible such a description as would enable a reader to understand the modern use of the electrocardiogram as a means of diagnosis. Prof. Waller has no ground of complaint in my references to other work of his in which results adding to our comprehension of the phenomena described were obtained. I am, Sir, yours faithfully,

June 27th, 1921. W. M. BAYLISS.

THE DEBT OF OUR TROPICAL DEPENDENCIES TO MEDICINE.

To the Editor of THE LANCET.

SIR,—All interested in the advance of tropical medicine and hygiene will welcome the prominence lately given to the much-needed recognition of their importance as essential and potent factors in the prosperity of our colonies and dependencies. Attention has rightly been drawn to the urgency of measures for prevention and treatment, and the call for research into the numerous problems presented by the extensive range of disease in the tropics. The baffling solution of many of these problems has been left too long to very occasional special commissions, or to the unaided and often thankless efforts of individual workers. It is, indeed, becoming more and more incumbent upon the Government not only to give wider support, by special sanction and State grant, to the elucidation and treatment of disease in the schools of tropical medicine at home, but also by establishing additional research and training institutions in our Crown Colonies, to assist the work of individuals, and to spread the gospel of hygiene among the native races. The very important medical side of our colonial missions, hitherto solely dependent on voluntary aid, has justly proved its claim to Government support. That this is the case has been well shown by Dr. J. B. Christopherson in an article on the medical work of the Universities' Mission to Central Africa, contributed to the society's journal of May, 1921. He emphasises the important rôle which this branch of the Mission has filled in the advance of tropical medicine, and the alleviation of the scourge of disease among the natives of our Central African colonies, thereby materially assisting the cause of colonial progress and development. Undoubtedly the wide field, open to the medical side of our missions, for preventive work and remedial treatment in such diseases as ankylostomia, bilharzia, yaws, malaria, dysentery, and sleeping sickness cannot be covered if relying entirely, as in the past, on inadequate voluntary subscription. As colonial administration reaps the benefit of the efforts of the Mission's medical workers, it is but just that financial support should be forthcoming from the Government to supplement and extend their valuable assistance in the prevention and treatment of tropical disease.

The educational aspect, particularly of the native in matters of tropical hygiene and causation of disease, though vitally affecting successful administration and the welfare of colonial populations, has been comparatively ignored. In the interests of the colonies concerned, as Dr. Christopherson rightly urges, much would be gained by popularising a scheme of elementary education for the native in the essentials of tropical disease and hygiene, and so ensuring his coöperation with medical endeavour in the task of rendering unhealthy regions habitable. For, clearly, the economic prosperity of tropical Africa is largely dependent on the country being made fit to live in, both for European and native. In this connexion medical science points out the surest way not only of achieving this object, but also of solving the labour question, a problem as vital in the tropics as it is at home, and therefore deserving of the fullest consideration by the governing authorities.

At a recent meeting of the Royal Society of Tropical Medicine and Hygiene, when an important paper was read by Dr. Claude Marshall on a new method of treating sleeping sickness by serum therapy, a vote was unanimously carried advocating that special representation be made to the Colonial Office, urging the provision of every facility for the investigation and trial of the method described. Among those taking part in the discussion was a distinguished visitor, His Excellency Sir Hugh Clifford, governor of the United Provinces of Nigeria, who spoke in high praise of the great debt which the colonies owed to the advances in our knowledge of the prevention of tropical disease. He laid particular emphasis on the importance of education in matters of health, and of the duty, attaching to all newcomers to the tropics, of acquiring a preliminary training in the fundamentals of tropical medicine and hygiene. It is greatly to be hoped that the unanimous feeling expressed at this meeting will produce very practical results in the guarantees of means of research into so widespread a disease as sleeping sickness, affecting, as it does, the welfare of a large native population, and, by its crippling influence on industry, determining, to no small extent, the commercial success and future of our African colonies. There seems good ground for belief that the Colonial Government authorities are fully alive to the interests at stake, and to the call for forwarding scientific research in the tropics by adequate and generous financial support. Will the Government meet that call?

Mr. Winston Churchill, Secretary of State for the Colonies, in his speech at the dinner given to the representatives of the Rockefeller Foundation, drew attention to the well-known achievements of scientific bodies in the alleviation of disease in all parts of the world, chief among them being the Rockefeller Foundation. He guaranteed that the Colonial Office would do all in its power to assist them in their great work; for the need of such help in the solution of problems of general health was fully realised, and the study of tropical disease, whether malaria or sleeping sickness, or the many other evils of the tropics, was, indeed, a work of mercy and urgency. Coming as it did from the Secretary of State for the Colonies, this assurance of the recognition of the need for help is a decided step towards attainment of the means to urther research in the vast field of tropical medicine, hether by Government grant or private endowment. Though primarily in the cause of humanity, Mr. Churchill might rightly have urged the expediency of colonial success as demanding earnest attention to the part played by sound and scientific knowledge of the prevention of disease in the tropics—the keystone of the future prosperity of our colonial empire responsibilities, and the foundation of successful colonial enterprise.

Too much reliance has been placed in the past on outside financial help in the cause of humanity and science, derived from the munificent spirit of individuals such as the late Sir Alfred Jones, from foundations such as the Rockefeller, and from our missionary societies. Without question the tropical side of the science of medicine and hygiene, dependent in considerable measure on these sources of help, has not only materially assisted colonial progress, but has established an indisputable claim to much-needed and indispensable financial backing from the State. The State should contribute, in proportion to the benefit it has received from science, and pay its share of what is justly speaking—a debt.

I am, Sir, yours faithfully,

J. Graham Forbes, M.D., F.R.C.P.

Harrington-gardens, S.W., June 23rd, 1921.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of The Lancet.

Sir,—Dr. E. Rowland Fothergill's letter in your issue of June 18th clearly shows that the profession is not united. I will go further and say that, except in a very superficial manner, neither the Federation of Medical and Allied Societies nor the British Medical Association can speak for any large body of medical men. Now if the General Medical Council could be largely increased by elected representatives, say 70 in number, surely that body would be able to represent the profession. It would require an Act of Parliament to make this increase in its numbers, but if the united body of doctors demanded it, it could be done.

This idea is one of the main objects of the National Medical Union, and it would encourage us to push the matter forward if medical men who agree with the idea would join the union, if not as members, then as associates paying little or nothing in the way of subscription. I am, Sir, yours faithfully,

E. H. Worth,

Hon. Sec., National Medical Union.

2, Aldrington-road, Streatham, S.W., June 19th, 1921.

A DISCLAIMER.

To the Editor of The Lancet.

Sir,—My attention has been directed to statements appearing in Great Britain to the effect that I gave evidence on the subject of the Prevention of V.D. before a Departmental Committee in 1912. The Committee may have had some of my publications in front of them, but I was neither asked for, nor have I given, any evidence in connexion with the inquiry. It is therefore not correct to say that my evidence had been considered.

I am, Sir, yours faithfully,

J. W. Barrett.

Melbourne, Australia, May 4th, 1921.

Donations and Bequests.—By will the late Sir Rowand Anderson left £1000 each to the Royal Infirmary, Edinburgh, the Royal Edinburgh Hospital for Incurables; and the Royal Edinburgh Hospital for Sick Children.—The late Mr. Thomas Fielding Johnson, J.P., of Leicester, bequeathed £1000 each to the Leicester Royal Infirmary and the Leicester Maternity Hospital; £500 to the Children's Hospital in connexion with Leicester Infirmary; £250 each to the County Home for Incurables, at Leamington, and the Charnwood Forest Convalescent Home; £200 each to the Institution for the Blind and the District Nursing Association; £150 to Dr. Barnardo's Homes; and £100 to the Wycliffe Society for Helping the Blind.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, JUNE 22ND.

The Dentists Bill.

THE House went into Committee on the Dentists Bill, the Earl of DONOUGHMORE in the chair.

Lord GREVILLE moved an amendment to Clause 1 (prohibition of practice of dentistry by unregistered persons) to provide that unqualified dentists should be placed on a separate register. He did not see how by adding unqualified men to a qualified list they were really increasing the number of qualified dentists. They would not help the shortage of dentists by transferring an unskilled man to a qualified list, because they did not make him any more skilled in the profession by so doing. All they did was to give him a false title and mislead the public. The placing of unqualified men on a separate list was strongly urged by the British Dental Association, but they were told by Sir Alfred Mond that if they pressed for it he would withdraw the Bill. They then agreed to the point, but that did not mean that the majority of qualified dentists agreed. He thought that his amendment was a very reasonable demand on the part of men who had spent several years in passing their examinations and in studying in hospitals in order to qualify for their profession. The unqualified man could start with merely a sign outside his door; and once he transferred to the register he obtained a great many benefits. One of the qualifications to be transferred to this list was "good personal character." That was no doubt a most estimable thing, but if they were told that in the absence of a qualified dentist some eminent divine was going to attend their teeth, they might derive great spiritual benefit, but he did not think they would obtain much physical consolation.

The Earl of ONSLOW said he had just received from the British Dental Association, which was to dentistry very much what the British Medical Association was to medicine, the following telegram:—

> "British Dental Association in annual meeting assembled at Bath this day unanimously support Dentists Bill as submitted by Minister of Health.—(Signed) STUART CARTER, President."

The number of persons actually practising dentistry who were not registered under the Act of 1878 was at least two to one of those registered under that Act and possessing dentistry degrees. It was quite a misapprehension to suppose that the Bill if passed as it stood would admit unqualified practitioners *en bloc* as qualified dentists.

The Marquess of SALISBURY: What will protect the public?

The Earl of ONSLOW said that they would be protected by the provision that these men must have practised for five out of the last seven years in this country, and so on. As regards the question of a separate title for those who possessed dental degrees, he (Lord Onslow) was proposing to move after Clause 3 a new clause which was primarily intended to prevent fraudulent representations by people describing themselves as something which they were not, and making it an offence for anyone to describe himself as a surgeon dentist unless he was in possession of a degree recognised by the Dental Board. All those persons at present on the register (except a very few persons still practising who were admitted by the Act of 1878, although holding no degrees) were holders of degrees in dental surgery, and would therefore have the exclusive right of calling themselves surgeon dentists. The Act of 1878 was very much less stringent than the present Act and admitted to the register all those who were practising dentistry at the time of the passing of the Act. This Bill proposed much stricter qualifications. The question of the register was not a new one. It was very carefully considered by a Committee of the Privy Council under the chairmanship of Mr. ACLAND. That Committee contained members representing every shade of opinion—qualified dentists, unqualified dentists, physicians, surgeons, civil servants, hospital authorities, and Members of both Houses of Parliament, and after the most careful examination of witnesses they came to the conclusion that this was a fair and just arrangement to the qualified dentists, to the unqualified dentists, and to the public. Unless the unqualified men were granted the full status of their brethren who possessed qualifications, how could it be expected of them that they would give up the free and unfettered position which they now occupied? He very much doubted whether Parliament would be willing to force them to do so if this amendment was carried, and the benefits which the Bill conferred might thereby be lost.

Viscount KNUTSFORD asked if their lordships had ever known the medical profession agree unanimously upon anything before? Yet they were unanimously in favour of this Bill, which a few lay people said was a great shame to them, because unqualified men were to be admitted on the same register as themselves. He was on the Committee to which the Government referred this question and when he saw his fellow members he felt certain of one thing—namely, that they would never come to an agreement. He was not certain that there would not be murder done before the end of their sitting, because they had on that Committee the head of the unqualified dentists, a member of the British General Medical Council, one of the leading lights among the qualified dentists, a doctor from the Ministry of Health, a doctor from the Ministry of Education, himself, as a layman, another layman, and a Socialist. But when they heard the evidence they were absolutely unanimous in recommending that the unregistered men should be admitted to the same register as the qualified men. The main reason was to place them under control and to stop all the malpractices which were going on among those men. All titles were misleading. The old Act tried to restrict the title. It said: "You must not call yourself a dentist, but you can call yourself a dental surgeon or a dental practitioner, or a dental specialist." No one, he contended, wanted this special list, and if the amendment were passed it would wreck a very useful Bill.

The Marquess of SALISBURY said that there had been a body of technical medical opinion hurled at their heads at which the bravest might quail, but he was not sure when they came to consider the thing very closely that the case was so formidable as it appeared. He had received a telegram from Scotland which said:—

> "Scotland agreed to the second reading in the Commons on the understanding that the amendments would be left to the unbiased decision of the Committee. The Government officially opposed amendments, despite understanding. Beg you to support Lord Greville in interests of good government and good faith.—MEDICAL DENTAL DEFENCE UNION, SCOTLAND."

Lord RIDDELL: Who are they?

The Marquess of SALISBURY said perhaps the noble lord knew better than he did. At all events he had concealed nothing. He had also a telegram addressed to another noble lord from Ireland: "Will you on behalf of Committee of Irish dentists please support Lord Greville's amendment to Dentists Bill this afternoon." So they were not quite certain about this volume of technical opinion being all on one side. But he wished to put in a word for the patients. It was very easy for technical people to come to an agreement, but what about the patients—the people who had toothache? Why should the present generation be handed over to unskilled dentists, because in the future there would be a better arrangement?

Lord RIDDELL said the Bill might necessitate certain anomalies for a temporary period, but it was well worth while to endure those evils in order to secure the good which would certainly result when dentistry had been placed on a proper footing as this Bill proposed to place it.

Lord SOUTHWARK thought that it would be a great misfortune if the Bill was lost through the insertion of amendments which might be opposed in the House of Commons.

The amendment was negatived, and the clause with minor amendments was agreed to.

The Earl of ONSLOW moved a new clause providing that a person registered under the principal Act—

> (a) shall by virtue of being so registered be entitled to take and use the description of dentist or dental practitioner;
>
> (b) shall not take or use, or affix to or use in connexion with his premises, any title or description reasonably calculated to suggest that he possesses any professional status or qualification other than a professional status or qualification which he in fact possesses and which is indicated by particulars entered in the register in respect of him.

The clause was agreed to.

Several other minor amendments were agreed to, the Committee stage of the Bill was completed, and the measure was reported to the House.

HOUSE OF COMMONS.

TUESDAY, JUNE 21ST.

Finance Bill—Spirits in Hospitals.

The House went into Committee on the Finance Bill, Mr. J. HOPE in the chair.

Mr. LEONARD LYLE moved the following new clause:—

> Section 4 of the Finance Act, 1918 (which provides for the reduction and allowance of duty in respect of spirits used in medical preparations or for scientific purposes), shall apply also to spirits used in hospitals on prescription, while Section 7, Subsection (1), of the Finance Act, 1920, shall not apply to wines supplied on prescription in hospitals, and the Commissioners of Customs and Excise may make regulations for carrying this provision into effect.

He said that he moved this clause last year on behalf of the hospitals, and he was afraid that the late Financial Secretary to the Treasury was fearful of what might happen to spirits in hospital once the cork had been taken out of the bottle; but he was putting this forward this year because there was now a different Chancellor of the Exchequer, who came from across the Border. He was hopeful that he would be slightly more sympathetic and less fearful of what might happen when the cork did come out of the bottle. The hospitals had to pay the full spirit duty, which was very heavy, and they were all very sympathetic towards the hospitals. During the war the Red Cross hospitals used to get their spirits at a much reduced duty, and he wanted to see that the hospitals which were so badly off just now got this small concession.

Mr. HILTON YOUNG (Financial Secretary to the Treasury) said it had never been possible to look at this proposal favourably from the point of view of the revenue. A considerable concession had been made to hospitals in regard to exemption on spirits actually used in medical prescriptions. This went a little further, and the great objection would be that it would constitute a very serious breach of the control of the Inland Revenue over the use of spirits. He thought if Mr. Lyle were acquainted with some of the opinions of the hospital authorities which had been prominently brought before him (Mr. Young) he would find that many responsible authorities were reluctant that they should undertake such difficult responsibilities as those proposed in the amendment. It was thought by a responsible body of opinion that the danger of abuse which would exist would not compensate the hospitals for the benefit they would derive pecuniarily from this exemption. For these reasons both in the interests of the revenue and of the hospitals he found it impossible to accept the new clause.

Mr. LYLE said he did not desire to divide the Committee on this occasion, but he would like to say that the British Hospitals Association quite approved of the amendment. He would, however, withdraw it.

The amendment was by leave withdrawn.

WEDNESDAY, JUNE 22ND.

Work of Consultative Health Councils.

Mr. LAWSON asked the Minister of Health whether he would supply a statement as to the work accomplished by the Consultative Councils appointed under the Ministry of Health Act, 1919.—Sir ALFRED MOND replied: The forthcoming annual report of the department for 1920-21 will include a statement on this matter.

River Lee Pollution.

Mr. G. W. H. JONES asked the Minister of Health whether his attention had been called to the pollution of the River Lee by sewage; whether he was aware that its present state constituted a menace to public health; whether he would take steps for the purpose of remedying the present state of affairs.—Sir ALFRED MOND replied: I am not aware that the present state of the River Lee constitutes a menace to public health, but if the hon. Member has any information to support the suggestion I shall be much obliged if he will supply me with it so that I may consider what action should be taken.

Washington Conventions.

Mr. CHAMBERLAIN (Lord Privy Seal), in reply to Major HILLS and Mr. GEORGE BARNES, said that he hoped that it would be possible to provide an opportunity for the further discussion that had been promised on the Washington Labour Conventions on Friday in next week, but that must not be taken as an absolute promise.

Medical Officers' Leave.

Sir MAURICE DOCKRELL asked the Secretary for the Colonies whether he could have extended to the Royal Army Medical Corps and Indian Medical Services the recent orders, General Routine Orders No. 24, of Jan. 10th, 1921, and No. 437, of May 4th, 1921, permitting officers other than those of the Royal Army Medical Corps and Indian Medical Services who had completed their time in Mesopotamia, and are due to serve a further period in India, such leave as they might be entitled to under existing leave rules before proceeding to India.—Lieut.-Colonel Hon. G. F. STANLEY replied: The question of the grant of leave to the officers referred to is a matter for the local military authorities. Officers of the Royal Army Medical Corps whose tour of foreign service is five years, serve two years in Mesopotamia and three years in India, and this procedure could not be carried out if officers were granted leave on the expiration of their period of service in Mesopotamia before transfer to India.—Sir MAURICE DOCKRELL: Why is there any differentiation between these medical officers and the ordinary combatant officers, and if they are to be sent after two years in the frying-pan of Mesopotamia to the fire of India for three or more years does the hon. gentleman not think they want cooling down, and will he send them to the hills for three or four months?—Lieut.-Colonel STANLEY: The question of difference between medical and combatant officers has always been same, that medical officers go for a certain tour of duty ad. As to the second part of the question, I am afraid add nothing to the answer I have already given.—Sir MAURICE DOCKRELL: I am pleading with the hon. and gallant gentleman that if he is sending them for three years to India he would allow them to be posted for three or four months in the hill country to give them a chance of getting their sea legs again.—The SPEAKER: The hon. gentleman had better put that question on the paper.

Consumption of Alcoholic Beverages.

Mr. KENYON asked the Chancellor of the Exchequer the consumption of beer, spirits, and wine in the United Kingdom during the quarters ending March 31st in the years 1918, 1919, 1920, and 1921.—Sir ROBERT HORNE (Chancellor of the Exchequer) replied: The following table shows the net quantities of beer, spirits, and wine retained for home consumption in the United Kingdom during the quarters ending 31st March in each of the years 1918, 1919, 1920, and 1921:—

	1918.	1919.	1920.	1921.
Beer, standard barrel	2,525,531	3,454,607	5,439,139	5,793,733
Spirits, proof gallon	3,271,000	3,766,000	6,363,000	4,436,000
Wine, gallon	2,929,000	4,795,000	5,565,000	2,838,000

THURSDAY, JUNE 23RD.

Dr. Addison's Salary.

The House went into Committee of Supply on a vote of £42,589 (including a supplementary sum of £6050) for salaries and expenses of Cabinet offices, &c., Mr. JAMES HOPE in the Chair.

Mr. LLOYD GEORGE (Prime Minister), in moving the vote, said that when the Government came to the conclusion after some reflection that it was necessary for some time to continue the post of Minister without portfolio it was done from no profligate desire to squander the taxpayers' money. He asked the House as a question of confidence in the Government to enable them to retain the services of Dr. Addison till the end of the session.

Lieut.-Colonel GUINNESS accepted a suggestion from the Prime Minister and moved the reduction of Dr. Addison's salary by £2,500.

Viscountess ASTOR defended Dr. Addison, who, she said, had only carried out at the Ministry of Health the policy of the Government and the policy which that House had passed. She was afraid that he had been a little too progressive for some people. She did not want to waste money; she wanted to save it. But there were things that were more valuable than money in the country, and one of them was public health. Some day hon. Members would have to face a different constituency and they would be told that they tried to do away with the Ministry of Health and they tried to do away with infant welfare organisations—things about which Dr. Addison cared deeply and for which he had worked hard.

After considerable debate, Mr. A. CHAMBERLAIN (Lord Privy Seal) moved the closure which was carried by 250 votes to 40.

Colonel GUINNESS's amendment to reduce Dr. Addison's salary by £2500 was then put and agreed to.

The State of the Voluntary Hospitals.

Sir ALFRED MOND, Minister of Health, announced that in view of the serious state of the voluntary hospitals the Government have decided to ask the House to vote a supplementary estimate of £500,000 in aid of deficiencies during the present year. The recommendation of the Cave Committee as to the control of such money by a Commission would, said the Minister of Health, be followed, and he proposed to appoint, as chairman of an *ad hoc* Commission for distribution, the secretary of the Ministry of Health, Lord Onslow. In reply to questions he stated that the Irish hospitals would not share in the distribution.

Inquiry on Light Artificial Limb.

Major COHEN asked the Minister of Pensions whether it was his intention to set up a court of inquiry to consider the question of the advantages of the light artificial limb.—Major TRYON replied: Yes, sir.

Pensions Administrative Expenses.

Mr. ROBERT RICHARDSON asked the Minister of Pensions the amount of administrative expenses of local war pensions committees for the year ending Dec. 31st, 1918, and Dec. 31st, 1920.

Mr. ALFRED DAVIES asked the number of persons employed on the staff of the Pensions Ministry on Dec. 31st, 1918, and Dec. 31st, 1920; and the number of persons receiving salaries of £500 per annum or over, including bonuses, on Dec. 31st, 1918, and Dec. 31st, 1920.

Mr. MILLS asked how many officials in his department at present received a salary of £1000, including war bonus, or over; and how many received a salary of £1000 or over in June, 1914.—Major TRYON replied: There can be no just comparison between 1918 and 1920. From 1918 onwards the work of war pensions committees was, as my hon. friends know, largely increased. Further, the staff of local committees which in 1918 was mainly voluntary is now employed on a salaried basis. In 1918, before the extension of the work due to demobilisation and other causes, the approximate amount of the administrative expenses of local committees was £500,000. In 1920 it was £1,200,000. This increasing expenditure was one of the reasons which actuated my right hon. friend in appointing the Departmental Committee of Inquiry over which I preside. As regards the staff in the direct employ of the Ministry the numbers on the dates mentioned in 1918 and 1920 were 9030 and 17,604 respectively, exclusive of hospital staff. The present number of officials (including 151 medical officers employed on a temporary basis) who are in receipt of salaries of £1000 a year or more, including bonuses, is 184. The number receiving £500 a year or over, including bonuses at the rates mentioned in 1918 and 1920, were respectively 208 (including 160 medical officers) and 680 (including 642 medical officers).

Regional Pension Awards.

Mr. WALTER HALLS asked the Minister of Pensions the number of pensions awarded by each region during the six months ending Dec. 31st, 1920, and the administrative expenses of each regional headquarters during the same period.—Major TRYON replied: 574,299 applications were considered during the period mentioned, 532,659 awards were made, and 41,610 claims rejected. The total expenditure for the regions incurred in administration during that period was 689,728.

The Committee on Adoption.

Sir JOHN BUTCHER asked the Secretary for the Home Department whether he had considered the Report of the Committee on Adoption; and whether he would soon be in a position to introduce legislation on the subject.—Sir JOHN BAIRD replied: The report of the Committee referred to which was issued last month is receiving consideration, but I am not yet in a position to make any statement as to legislation.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful:—

THIRD EXAMINATION FOR MEDICAL AND SURGICAL DEGREES.

Part I., Surgery, Midwifery, and Gynæcology.—G. F. Abercrombie, A. C. Ainsley, F. Allen, S. H. Barnett, C. C. Beney, E. M. Burrell, W. R. Carling, C. N. Carter, A. O. Courtis, D. Crawford, C. Dunscombe, D. D. Evans, L. E. Frazer, H. J. H. Hendley, R. C. Hewitt, B. E. Jerwood, A. V. Johnson, P. B. Kittel, R. B. P. Lansdown, S. Orchard, E. S. Orme, F. A. Phillipps, J. H. Porter, W. Shaw, G. W. Theobald, G. I. F. Tweedie, D. C. L. Vey, J. P. Wells, C. E. Whitting, C. H. Whittle, and H. L. Willey.

Part II., Medicine, Pathology, and Pharmacology.—A. C. Ainsley, A. E. Clark-Kennedy, B. K. T. Collins, H. T. Cubbon, E. Donaldson, N. D. Dunscombe, V. N. Fenton, E. A. Fiddian, C. I. C. Gill, W. S. Gross, E. A. H. Grylls, G. Habgood, A. T. Hawley, E. C. Malden, L. B. Maxwell, R. A. Olphert, W. H. Palmer, H. A. A. Pargeter, F. A. Phillipps, P. W. Putnam, W. Raffle, A. P. Saint, W. Shaw, T. H. Somervell, E. D. Spackman, H. N. Stafford, R. A. P. Starkie, S. D. Sturton, G. W. Theobald, G. D. C. Tracy, R. R. Traill, Y.-S. Wan, and C. H. Whittle.

EXAMINATION FOR DEGREE OF M.CH.

J. B. Hunter.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on June 22nd Sir Sydney Russell-Wells, M.D., was re-elected Vice-Chancellor for the year 1921–22.

Grants were made out of the Dixon Fund for the year 1921–22 as follows: Mr. F. J. F. Barrington, M.B., B.S., for research on the nervous mechanism of micturition, £50. Mr. E. J. Evans, B.Sc., for researches on the nature of the discharge in an X ray tube with a static machine as source of potential, £15. Prof. J. P. Hill, D.Sc., F.R.S., for researches on the development of Mammalia, more particularly of the Primates, £40. Miss G. Z. L. Le Bas, B.Sc., for researches into the part played by lipoids in immunity and bacteriological intoxication, £40. Mrs. M. M. Neilson-Jones, D.Sc., for researches on mycorhiza and the physiology of heterotrophic nutrition in flowering plants, £50. Prof. Karl Pearson, M.A., F.R.S., to defray the cost of the publication of drawings of the sesamoid bones of the knee-joint to be used to illustrate a memoir on the subject now in progress, £50. Mr. J. W. D. Robinson, M.Sc., for geological research on the palæozoic beds of south-east England and north France, £30. Mr. D. M. Shaw, to enable him to apply and demonstrate his special "Theory of Maximum Shear" in the functional interpretation of specific tooth-shapes and the normal physiological mechanism and interactions of teeth, especially the teeth of man, £45. Mr. H. G. Smith, B.Sc., for investigation of the Basic intrusions of Central Wales, £51. Miss D. M. Wrinch, D.Sc., for researches on the morphological significance of nodal points on the branching of trees, £50.

The following appointments were made: The Vice-Chancellor (Sir Sydney Russell-Wells), the Principal Officer (Sir Cooper Perry), Dr. H. C. H. Carpenter, F.R.S., and Prof. E. A. Gardner to be Governors of Birkbeck College. Miss E. C. Higgins to be Governor of Grey Coat Hospital. Mr. S. L. Loney to be Member of the Surrey Education Committee. Sir Sydney Russell-Wells to be representative at the Conference of the International Union against Tuberculosis to be held in London in July, 1921. The Scholarships Committee reported the appointment for 1921-22 of Mr. E. C. Warner, of Guy's Hospital Medical School, to the University Studentship in Physiology of the value of £50.

UNIVERSITY OF MANCHESTER.—Alderman Henry Plummer, a member of the Court of Governors and of the Council of the University, has contributed the sum of £1000 to the University Appeal Fund in commemoration of his golden wedding. The following have been recommended for the M.D. degree: Basil Browning, T. E. Dickinson, W. H. Kauntze, R. L. Newell, J. A. Panton (gold medallist), Harry Platt (gold medallist), and D. McK. Sutherland.

EPSOM COLLEGE.—The sixty-eighth annual general meeting of the Governors of Epsom College was held on June 24th, at 49, Bedford-square, London, W.C., Sir Henry Morris, the treasurer, presiding. The report of the scrutineers showed that the successful applicants for Pensionerships and Foundation Scholarships are: Pugh Pensionership, Mrs. Margaret Bromilaw; Christie Pensionership, Dr. Peter W. McGregor; Sir Thomas Smith Pensionership, Mrs. Celeste S. M. Orme; Foundation Scholarships, Frederick J. Brice, David Joy, John L. Newton, Philip M. Lawson, Spenser G. F. Penny, Eric R. Bent, James D. Shoolbread. In moving the adoption of the report the treasurer referred to the great loss which the College had sustained in the death of Sir Frederick Taylor, who had been for over 30 years an active member of the Council, and for many years had held the offices of chairman of the School Committee and honorary physician. He thanked friends of the College who had responded to the Council's application to take Mortgage Debenture Bonds of £100 at 5 per cent. interest, and stated that £20,200 of the Debentures had been allotted to date. As a result the Council had repaid the £14,000 owing on Mortgage, and had liquidated the greater portion of the debt to the bankers. This debt was incurred owing to the greatly increased cost of maintaining the school prior to the time when the higher school fees became payable, the provision of an annexe to the College infirmary, and the expense of entering upon new premises as a result of the expiration of the lease of the former London offices. The chairman further referred to the fact that the Epsom College scales of remuneration for assistant masters compared very favourably with the scales suggested in the Burnham report, and pointed out that the Council had instituted a non-contributory scheme of superannuation allowances for the masters which was far more generous than the contributory scale adopted 17 years ago. Schemes had also been instituted for providing pensions for other officials. The report having been adopted, formal business was transacted, after which a cordial vote of thanks to Sir Henry Morris was proposed by Sir William Church, seconded by Dr. P. W. Latham, and carried by acclamation.

DISTRICT NURSING OF INSURED PERSONS.—Considerable discussion is taking place as to the nursing of insured persons in their own homes, and as to contributions to nursing associations by approved societies. The voluntary organisations for these purposes may receive contributions from the societies, either under their statutory powers under paragraph 20 of the Act of 1911 or by way of additional benefits out of their surplus funds. The Central Council for District Nursing in London (Chairman, Sir William Collins; Chairman of the Executive Committee, Mr. E. B. Turner) in April last informed those approved societies with members resident in London that the Council was in a position to arrange for adequate nursing for all such members, and invited the societies to make contributions in aid of this work. The Ministry of Health, in a circular issued to approved societies, contemplates sanctioning schemes for bringing into operation additional benefits in the course of next month, and is prepared to furnish societies with model draft schemes to that end. Among additional benefits suggested by the Ministry is provision of a nursing service for members of the societies, for which purpose a separate fund may be set aside. Lord Cave's Committee's report on the voluntary hospitals, while recognising the complete freedom of discretion of the approved societies in granting financial aid in respect of insured persons to voluntary hospitals, appears to favour a contribution or donation in recognition of such services to their members, rather than any scheme of insurance by payment in advance (with its contractual implication), or compulsory payment afterwards in respect of service rendered. Here, again, the case of the District Nursing Associations is analogous with that of the voluntary hospitals in relation to insured persons or approved societies, and any scheme of financial aid to the one may be applied to the other.

Society of Medical Officers of Health: Proposed Midland Tuberculosis Sub-Group.—A meeting for medical officers working in tuberculosis in the Midlands will be held on Saturday, July 9th, at 3 p.m., at the tuberculosis dispensary, 44a Broad-street, Birmingham, with the object of considering the advisability of forming a Midland Tuberculosis Sub-Group. Dr. G. B. Dixon, chief T.O., of Birmingham, will attend. Those interested in the work of prevention and treatment of tuberculosis, whether members of the society or not, are desired to attend this meeting. If a sub-group is formed sub-group rules and election of officers will be considered.

Royal Sanitary Institute.—The Congress of the Royal Sanitary Institute, at Folkestone, passed off successfully last week. It evoked considerable interest, and was attended by upwards of a thousand delegates and members. Lord Radnor, the President, at the inaugural meeting on the Monday, dealt with the value of the voluntary services. Amongst the many topics discussed perhaps the milk question was one of the most prominent. The conference of veterinary inspectors made it clear that little progress has been made in the last 25 years in reducing the prevalence of bovine tuberculosis. Resolutions were passed for the encouragement of grade A milk and for the adequate control of methods of pasteurisation. Opinions were expressed that the only safe milk on the market at present for infants and little children, practically speaking, is dried milk. Grade A milk is not available, and pasteurisation may mean anything. Dr. Mellanby's popular lecture emphasised the need for a greater consumption of milk, showing that to double the national consumption of milk would be wise, and that there is room for all the "milk reformers'" efforts to get a safe milk. The deplorable state of the teeth of the nation received a good deal of attention at the Congress, and in this connexion the popular lecture aroused great interest, and most of those who attended the lecture were agreed that Prof. Mellanby and his wife have proved their case that by a change of dietary an enormous advance could be made at once in the present state of our knowledge not only in preventing rickets, but in securing good teeth.

A special section of the Congress dealt with the subject of Industrial Welfare, as essential to attaining a better spirit in the relations of capital and labour. The clarification of the air, as the result of the coal dispute, gave a stimulus to the discussion on smoke prevention, the remarks of the various speakers showing clearly how small was the effort throughout the country to tackle this problem.

Among other subjects dealt with there was an interesting discussion on the education of backward children, and another on the tests for mentally defective children.

The difficult question of housing received little attention, doubtless because at present this is regarded more as a problem for the statesman than for the sanitarian.

The late Colonel S. H. O'Brien Banks.—The death occurred at Brighton, where he had resided since 1909, on June 15th, of Colonel Samuel Henry O'Brien Banks, F.R.C.S. Irel., late I.M.S., at the age of 79. A native of Ireland, his father was Dr. Henry Banks of Co. Wicklow, a well-known Irish physician, while Sir John Banks, Queen Victoria's physician in Ireland and Regius Professor of Medicine at Trinity College, Dublin, was his uncle. Samuel Banks studied medicine at the Carmichael College of Medicine, and the Richmond, Whitworth, and Hardwicke Government Hospitals, Dublin, and was the Carmichael Prizeman for two years. He took his degrees in 1865 and 1866, and in 1880 became a Member of the King's and Queen's College of Physicians and a Fellow of the Royal College of Surgeons, Ireland. The greater part of his medical career was spent in India. In 1866 he joined the Indian Medical Service, and in the following year sailed from Bombay for Abyssinia, took part in the campaign against King Theodore, and was present at the storming and capture of Magdala on April 13th, 1868. For his services he was awarded the Abyssinian medal. He subsequently held a number of important appointments lia. For some time he was a civil surgeon at Hyderabad, Deputy Surgeon-General in Bombay, and served on mbay Government Council as chief medical member. He was also a magistrate for Bombay. He retired in 1896 on a well-earned pension with the rank of Colonel, and lost his only son in the second battle of Ypres.

Federation of Medical and Allied Societies.—The annual general meeting was held at 11, Chandos-street, London, W., on June 28th. In the unavoidable absence of the president, Sir Berkeley Moynihan, the vice-president, Sir Malcolm Morris, delivered the annual address. The annual report was read, and officers were appointed for the ensuing year. Thirty societies were elected to representation on the Executive Council, and after a ballot Dr. Ford Anderson was elected as a representative of individual members. The meeting of the Executive Council was held before the annual meeting, Sir Malcolm Morris presiding. A report was received from the Medical Council concerning the question of pressing for an inquiry into the medical provisions of the National Insurance Acts. The General Purposes Committee reported on a reference it had received regarding the publication of the news of the Federation, and it was resolved to issue a Journal, the arrangements being left in the hands of a special committee appointed for the purpose. The transfer of the offices to new premises, at 12, Stratford-place, London, W., was authorised.

London Federation of Infant Welfare Centres.—The annual meeting was held at the Mansion House on June 29th. Sir Alfred Mond was present and spoke on the work of infant welfare centres as a whole. He said that he knew of no movement which had produced more immediately valuable results for relatively so small an expenditure as these centres. Whatever economies had to be made, and unfortunately we lived in an age of economy, he expressed the hope that the last direction in which economy would be attempted would be the curtailment of that important part of preventive medicine. Sir Alfred Mond added that the only true economists in the world were women, and he looked to women for guidance as to the extent to which it was possible to achieve more in the infant welfare movement without an increase in expenditure. Sir Arthur Stanley expressed satisfaction that after combining in their work for two years the British Red Cross Society and the Infant Welfare Organisations showed no tendency to drift apart, but rather to draw closer together.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.

The sixth annual meeting of the National Council for Combating Venereal Diseases was held in the Barnes Hall, at the house of the Royal Society of Medicine, 1, Wimpole-street, W., on June 28th.

In the course of his Presidential address Lord Gorell said that during the past year branches of the National Council had been very active; there had been an increasing number of attendances at treatment centres, and the public was evidently realising the importance of continuous treatment. On the home side of the work, in one county alone lectures had been delivered to more than 30,000 people; in spite of criticism of this form of propaganda it was clear that much must be done by bringing home the facts of venereal disease to such a large number of people. Medical assistance must be accompanied by this method of going to the root cause of the evil. On the imperial side a substantial beginning of similar work was evident, and on the international side, whatever opinions might be held concerning the general utility of the League of Nations, there could be no doubts on the desirability of the work of the International Health Section, at whose recent Conference, held at Genoa, the National Council had been represented. The National Council, moreover, was now the recognised agent of all venereal diseases work carried on under the auspices of the Joint Committee of the Red Cross and the Order of St. John. When in May the Council met representatives of the Crown Colonies and of the seafaring trades all those who attended saw the necessity for amendment of the Merchant Shipping Act with reference to venereal diseases; and under the auspices of the Colonial Office, with the assistance of the Ministry of Health, three Commissions were despatched to the ports of the Empire to investigate the conditions obtaining there and to rouse public opinion in the matter.

Prof. Winifred Cullis, of the Mediterranean Commission, speaking of the work done by that Commission at Gibraltar and Malta, expressed the feeling that here was an opportunity to repay a small part of the debt owing to the merchant service for its services during the war. The Commission had advocated "out-patient" facilities, whereby sailors might remain in their ships, but by carrying medical cards with them might obtain continuous treatment at successive ports of call, and "in-patient" treatment which would dispense with the hardship now attendant upon the seaman forced by illness to leave his ship. The establishment of out-patient departments was promised at both ports, and branches of the National Council formed; although prostitution is officially sanctioned at Malta there were signs that a change of policy might soon be made in that respect.

Dr. A. F. Wright, of the Western Commission, emphasised the extraordinary temptations to which sailors are exposed at many ports, and the necessity not only of means of treatment on every ocean-going ship, but of special competence on the part of every ship's doctor to deal with venereal disease. The Commission met with different receptions in various West Indian islands; in some, where the population was comparatively large, conditions of public health were good, but in the poorer and smaller islands not only venereal diseases, but all forms of public health work were disgracefully neglected; and this was not altogether the fault of the medical profession. The lack of coördination between the islands, each of which had its own government, was productive of disastrous results; the whole tone of medical arrangements needed raising before venereal disease could be properly considered and treated. Many West Indian doctors were brilliant general practitioners, but there were apparently no experts in the whole of the West Indies, and the lack of laboratory arrangements, with the consequent almost complete neglect of bacteriology, together with the very urgent need for post-graduate instruction of men sometimes twenty years behind the times in medicine, rendered the state of affairs very serious.

Mrs. Neville Rolfe, General Secretary of the Council and a member of the Eastern Commission, spoke of observing in the places visited a lack of recognition of the whole idea of public health vital from the social and economic points of view. At Hong-Kong the conditions of the port were such that it was miraculous that any seamen escaped venereal disease; even the vessels of the Navy could only with great difficulty be kept clear of women, and both there and at Singapore strong commercial interests had grown up which opposed every movement to prevent venereal disease on the score of interference with trade. At Colombo an efficient port administration protected the shipping; at Shanghai the procedure of government, consequent upon the status of the city as a Treaty Port, rendered legislation difficult to obtain, but the Chinese Chamber of Commerce had arranged to translate and print in Chinese many of the pamphlets issued by the Council; since the return of the Commission a venereal diseases specialist had been sent for, and a clinic was to be opened in the port.

The Chairman of the Executive Committee of the South African National Council for Combating Venereal Diseases, in proposing a vote of thanks to the speakers, spoke of the complications introduced into the problem in South Africa by the questions of race, language, and colour. Much propaganda work was done by pamphlets, but lecturers were hard to obtain. The Public Health Bill of 1919 had put an end to the recognition of prostitution. The meeting concluded with a vote of thanks to Lord Gorell, proposed by Mr. E. B. Turner, and carried by acclamation.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, July 4th, at 8.30 p.m.

Resumed Discussion (open) (the President, Sir John Bland-Sutton, in the chair) on

"The Problem of the Private Clinic System in Great Britain."

If thought desirable the following resolution may be moved:—

That in the opinion of this meeting the time is ripe for the formation of Group Clinics in this country, and that sympathetic encouragement should be given to them by the profession and by its governing bodies.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

Thursday, July 7th.—8.15 p.m., Annual General Meeting. Election of Officers and Council for Session 1921-1922. 8.30 p.m., Paper:—Prof. A. Louise McIlroy: Some Factors in the Control of the Birth-rate. Followed by a discussion.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, July 4th.—12.15 p.m., Dr. Burnford: Pathological Demonstration. 2 p.m., Mr. D. Armour: Operations. 2.30 p.m., Dr. A. Saunders: Demonstration of Cases (Medical Wards). 5 p.m., Lecture:—Mr. D. Armour: Diseases of the Gall-bladder and Ducts—Treatment.

Tuesday.—10 a.m., Surgical Registrar: Demonstration of Cases. (Surgical Wards.) 12 noon, Mr. T. Gray: Demonstration of Fractures. 2.30 p.m., Mr. Addison: Visit to Surgical Wards. 5 p.m., Lecture:—Mr. Baldwin: Surgery of the Rectum.

Wednesday.—12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 p.m., Mr. D. Armour: Demonstration of Cases. (Surgical Wards.) Mr. Addison: Operations. 5 p.m., Lecture:—Dr. Simson: Sterility.

Thursday.—10.30 a.m., Dr. Simson: Gynæcological Demonstration. 12 noon., Dr. S. Pinchin: Diseases of the Heart. 5 p.m., Special Lecture:—Dr. L. Williams: Vitamins and Internal Secretions. (Open to all Medical Practitioners.)

FRIDAY.—10 A.M., Dr. G. Stewart: Neurological Demonstration. 12.15 P.M., Dr. Burnford: Applied Pathology. 2.30 P.M., Mr. Baldwin: Operations. Dr. Pritchard: Visit to Medical Wards. 5 P.M., Lecture:—Mr. Addison: Inflammation and Tumours of the Breast.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases. (Medical Wards.)

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 4th.—10 A.M., Mr. W. E. Tanner: Surgical Out-patients. 2 P.M., Dr. A. J. Whiting: Medical In-patients. 2.30 P.M., Mr. J. B. Banister: Gynæcological.

TUESDAY.—9.45 A.M., Lt.-Col. R. H. Elliot: Eye Operations and Cases. 2.30 P.M., Dr. J. Metcalfe: X Ray Department. 3 P.M., Lecture Demonstration:—Mr. C. H. Hayton: Cases illustrating Diseases of the Larynx (1) Inflammatory, (2) Destructive.

WEDNESDAY.—2 P.M., Mr. C. H. Hayton: Throat Operations. 2.30 P.M., Dr. W. J. Oliver: Dermatological. 3 P.M., Lecture Demonstration:—Mr. W. E. Tanner: Specimens illustrating Some Common Affections of Joints.

THURSDAY.—2 P.M., Mr. N. Fleming: Eye Department. 2.30 P.M., Mr. J. B. Banister: Gynæcological Operations. Dr. J. Metcalfe: Radiology.

FRIDAY.—2 P.M., Dr. C. E. Sundell: Diseases of Children. 3 P.M., Lecture Demonstration:—Dr. C. E. Sundell: Breast Feeding. Weaning. 5 P.M., Dr. Provis and Mr. Benians: Venereal Department.

SATURDAY.—10.30 A.M., Mr. W. E. Tanner: Operations. 3 P.M., Mr. H. W. Carson: Surgical In-patients.

UNIVERSITY OF LONDON.

The Semon Lecture will be given in the Lecture Hall of the Royal Society of Medicine, 1, Wimpole-street, W.

TUESDAY, July 5th.—5 P.M., Dr. W. Jobson Horne: The Relationship of the Larynx to Pulmonary Tuberculosis.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Turner-street, Mile End, E.

SURGICAL UNIT.—A Special Course of Ten Lectures on Advanced Surgery in the Unit Theatre to Post-graduates and Senior Students.

TUESDAY, July 5th, and THURSDAY.—4.15 P.M., Mr. H. S. Souttar: Injuries of the Peripheral Nerves.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.

Post-Graduate Course on Infant and Child Welfare.

A Course of Twelve Practical Demonstrations on the Management and Feeding of Infants and Young Children by Dr. E. Pritchard to Qualified Practitioners.

TUESDAY, July 5th.—10.30 A.M., Demonstration VII., The Management of Difficult Cases.

THURSDAY.—3 P.M., Demonstration VIII., Treatment of Minor Ailments.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, July 7th.—4 P.M., Lecture:—Dr. F. Langmead: Pulmonary Tuberculosis.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock-square, W.C.

A Course of Ten Lectures on Elementary Psychotherapy, to be given by Dr. H. C. Miller, at the Kingsway Hall, Kingsway, W.C.

FRIDAY, July 8th.—5.15 P.M., Lecture X.: Herd Instinct and Herd Ideal: Mob Hysteria: Rumour.

Appointments.

DODD, H. G., M.B., B.S. Durh., has been appointed Honorary Anæsthetist, Royal Alexandra Hospital for Sick Children, Brighton.

HAIRE, N., Ch.M., M.B. Sydney, Clinical Assistant, Out-patient Department for Women and Children, London Lock Hospital.

SHEEN, A. W., M.S. Lond., F.R.C.S. Eng., to the new chair of Professor of Surgery in the Welsh National School of Medicine.

Certifying Surgeons under the Factory and Workshop Acts: THOMAS, T. P., M.R.C.S., L.R.C.P. Lond. (Brecon); ALLEN, E. H. C., M.B., B.Ch. Dub. (Clwt-y-Bont).

Vacancies.

THE Chief Inspector of Factories announces the following vacant appointments: Milngavie (Dumbarton); Pitlochry (Perth).

Births, Marriages, and Deaths.

BIRTHS.

COOKE.—On June 18th at Berkshire Villa, Ventnor, the wife of Reginald T. Cooke, M.R.C.S., L.R.C.P., of a daughter.

EDMONDS.—On June 25th, at Manor House, Gleneagle-road, Streatham, the wife of C. J. E. Edmonds, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

IEVERS.—On June 20th, at a nursing home, Sandgate, the wife of Brevet Lieut.-Colonel Osburne Ievers, D.S.O., R.A.M.C., of a daughter.

JAMES.—On June 3rd, at Mussoorie, India, the wife of Major J. F. James, I.M.S., of a daughter.

MARRIAGES.

BARTER—KIES.—On June 22nd, at St. Michael's Church, Stockwell, Lieut. J. A. Barter, R.N., to Pauline Kies, late L.M.S., Shanghai.

EDWARDS—JONES.—On June 25th, 1921, at Bryn Du (C.M.) Church, Llanfaelog, Anglesea, Thomas P. Edwards, M.D., B.S. Lond., D.P.H. Cantab, Ardwyn, Ruthin, N. Wales, to Eveline, daughter of the late D. H. Jones (of Carnarvon), and of Mrs. Jones, Morianfa, Rhosneigr, N. Wales.

MCEWAN—HART.—On June 22nd, at the Parish Church, Troon, George C. McEwan, M.B., D.P.H., to Ruth Margaret, younger daughter of the late Mr. Robert Hart and Mrs. Hart, Frognal, Monkton, Ayrshire.

DEATHS.

BELL.—On June 25th, at The Lindens, Torquay, William Riddall Bell, M.D., in his 86th year.

COW.—On June 23rd, at Redruth, Cornwall, Douglas Vernon Cow, M.D. Cantab., of Great Shelford and Cambridge.

WALLIS.—On June 26th, at Old Stone House, East Grinstead, Percy Evershed Wallis, M.R.C.S., L.R.C.P., aged 68

Notes, Short Comments, and Answers to Correspondents.

A STUDY OF THE NUTRITION AND ECONOMIC CONDITIONS OF WORKING-CLASS FAMILIES IN GLASGOW IN APRIL, 1921

BY ANNABEL M. T. TULLY, M.A.

(From the Department of Physiology, University of Glasgow.)

INTRODUCTION BY PROFESSOR NOËL PATON, M.D., F.R.S.

IN a paper published in THE LANCET of March 5th, 1921,[1] an account was given of an investigation of the condition of nutrition of the working classes in Vienna under post-war conditions. It was shown that the food consumed in 40 typical working-class families was far below that required by those engaged in manual work, and was insufficient to maintain normal growth in children.

It is of no little interest to compare the condition of these families with that of the poorer working classes in this country, under present conditions when unemployment is rife; and, in order to enable such a comparison to be made, Miss Tully has carried out a careful investigation upon 11 typical families in Glasgow. These families were neither better nor worse off than thousands of others round about them and the results may safely be accepted as giving a fair representation of the general condition of this part of the population. The fathers and mothers were generally steady and at least ready to face the right to work as a basis of the right to live.

The results recorded are sufficiently disconcerting. In considering them, it must be remembered that a man resting in bed expends energy at the rate of about 1700 calories per day; one leading an absolutely sedentary life expends some 2500 and, when working hard, some 4000 calories. The energy supplied in the food is not all available, some 10 per cent. is lost in digestion, so that, to supply 2500 calories net the food must contain 3000 gross.

In only two of the 11 families did the diet yield energy equivalent to 3000 calories, and this was obtained only by the expenditure of more than the whole income for the week on food—i.e., by borrowing, or selling, or pawning the family belongings. In six families only about 2500 calories were secured—i.e., about 2250 net—but again, only by over-expending the income on food or from charitable help. In three families the conditions were worse than in the majority of the Viennese families, the food yielding an energy supply of only between 1600 and 1800 calories (about 1530 net) per man per day. In seven of the families unemployment relief in some form was received.

Evidently, even when the demand for energy is reduced by the want of work, a supply of food yielding about 2500 calories must be got to maintain existence and in most of these families it is obtained by sacrificing expenditure on everything else. Some are unable to procure even this all too inadequate amount of nourishment.

THE STUDY OF DIETARIES.

During April, 1921, a study was made of the dietaries of 11 typical labouring class families in Glasgow, with the view of ascertaining the effect of the present trade depression upon their food consumption. A general strike of coal miners was in progress, and the fathers were either out of work or on short time. This is a continuance of the series of dietary studies carried by Miss Ferguson[2] upon the same class during the war, all of which form supplements to the more exhaustive study made in 1911–12 by Miss Lindsay.[3] The method of study and the source of the food analyses were those used by Miss Lindsay and Miss Ferguson. In each case the food was weighed and the waste collected for the period of a week as described in reference (2). The studies included 12 men, 11 women, 34 children under 10 years of age and 11 children over 10—68 persons in all.

To make the results of the various families comparable and to render a comparison with the previous observations possible, the food is expressed as that consumed per unit of population—i.e., per man per day, taking the requirements of women and children at the usual proportion of those of a man (Lusk's table).

Proportionate Food Requirements of Men, Women, and Children.

Males, above 13	1·0
Females, above 13	0·83
Children, 6 to 12	0·6
Children, below 6	0·5

Thus, a family of—

Father	1·0	Boy (8)	0·6
Mother	0·83	Girl (4)	0·5

would correspond to 2·93 men. Three meals are taken as one day and meals taken outside are, of course, deducted.

In Table I. families are grouped according to income, above or under 8s. per man per week.

One of the docker's families (No. IV.) consented to a second study during May when the father was on strike and consequently receiving only £1 weekly from the Dockers' Union. A comparison of results is given in Table II.

As is seen from Table II., in this family in May more than double the weekly income was spent on food, and, as none of the weekly provisions were obtained on credit, the money to pay for these goods was raised by loans from friends.

The energy values differ little in the two groups, but in the poorer families a larger proportion of energy is got from carbohydrates.

TABLE I.—THE RELATION BETWEEN DIETS AND INCOME.

Families having over 8s. per Man per Week.

No.	Diet per man per day.				Income.					Number in family.			
	Calories.	Protein.	Fat.	Carbohydrate	Total income.	Per man per week.	Amount spent on food per man per week.	Per cent. of income spent on food.	Energy value purchased per 1d.	Males above 13.	Females above 13.	Children.

XI.	1775	50·0	61·2	241·1	0 13 0	5 6¾	4 3½	20·8	221·8	1	1	—	1
Average	2505	61·1	73·3	380·4	1 9 5	6 10½	6 1¾	—	219·8	—	—	—	—

* The small percentage of the income spent on food was due to the fact that a considerable amount was being paid in liquidating outstanding debts; the proportion of *available* income spent on food was much higher.

Table II.—Re-Study of Family IV.

—	Diet per man per day.				Income.				
	Calories.	Protein.	Fat.	Carbohydrates.	Total income.	Per man per week.	Spent on food per man. per week.	Per cent. income spent on food.	Energy value purchased per 1d.
					£ s. d.	s. d.	s. d.		
April ..	2999	99·8	94·4	417·6	3 12 0	11 11½	8 5½	72·2	232·3
May ..	2810	87·6	65·5	449·1	1 0 0	3 3¼	7 5½	228·7	215·6

These tables show—what has been emphasised in previous studies of the social conditions of the very poor—that food, the supply of energy, is the first charge upon income, that this must be provided and that all other expenditure must be subordinated to it. Under present conditions an adequate supply is impossible. Comparison of the present situation with that in previous years is given in Tables III. and IV.

Table III.—*Average Energy Value of the Diets.*

Date.	No. of families.	Energy in calories per man per day.	Protein in grms. per man per day.	Fat in grms. per man per day.
1911-12 ..	60	3163	110	83
1915-16 ..	40	3298	102	90
April, 1921 ..	11	2181	68	75

Table IV.—*Energy Value Purchased per Penny.*

Date.	No. of families.	Energy value (1*d.*)	Date.	No. of families.	Energy value (1*d.*)
1911-12 ..	60	453	Nov., 1917	8	264
1915-16 ..	10	350	Dec., 1919	5	210
Feb., 1917	10	274	April, 1921	11	198

In spite of careful marketing by most of the mothers, the energy purchasable per penny shows a marked decline from previous years. Nothing could more clearly indicate the serious effect of the present economic situation.

Housing.

Most of the families are living in very poor overcrowded quarters. The conditions may be briefly stated as follows:—

Group A.

Average number of rooms	1·1
Average number of inmates	5·8
Average air space per person	337 cub. ft.
Average rent per week	6s.

Group B.

Average number of rooms	1·5
Average number of inmates	6·5
Average air space per person	309 cub. ft.
Average rent per week	6s. 6½d.

Condition of the Children.

The economic depression has not lasted for many months and has hardly had time to tell upon the physical development of the children. The accompanying table (Table V.) shows their condition. Since malnutrition tells first upon weight, this alone is dealt with.

The children of only one family (VII.) reach the anthropometric standard weight. This family has been accustomed to better circumstances, and it is one of the families which had over 3000 calories per man per day. The others have been more or less constantly in financial straits. The average deficiency in weight below the anthropometric standard for Group A (14 children) is 13·4 per cent.; for Group B (16 children) 17 per cent.; for all (30 children) 15·9 per cent. In Miss Ferguson's[4] study in 1918 the deficiency was 13 per cent.

In conclusion, I should like to thank the students of the class of physiology who so kindly helped by visiting the families, and very specially Professor Paton for the assistance which he has given me.

Appendix of Family Histories.

1. Father, a labourer; has been out of work for months, but did a little work in February; in addition to unemployment money family get 15*s.* food tickets weekly from the Lord Provost's Fund; during study father got work as a night-watchman (£2 5*s.* weekly) but would not be paid till the following week. House is very clean; rent in arrears. Children quite healthy. Father suffers from bronchitis, the effect of mustard-gas poisoning. Mother not very strong—frequent headaches.

2. Father, a carter; unemployed for several months; has a pension of 17*s.* 3*d.* weekly. House clean though very bare. Greater part of income seems to go in repaying loans. During the study two pints free milk daily was granted by the Corporation. General condition of children is fair; baby is delicate and older child suffers from pains in the head, the result of a fall. The mother is thin and ill-looking; boils on her arms. Father is very deaf, owing to a wound received in the army.

3. Father, a carter; unemployed since Christmas. Family receive 10*s.* weekly food tickets from Lord Provost's Fund. Very poor home; all the furniture in pawn; relatives occasionally give assistance. Children all in fairly good health except one child (3 years), very pale and thin.

4. Father, a docker; until week of this study has had very little work, one or two days per week at most; 4½ days during study. House is rather untidy but quite clean. Children are rather delicate; two have rickets; child (4) has eruption on face; child (8) is lame owing to an abscess on leg. Mother is thin and unhealthy-looking.

5. Father, a docker; working only one or two days weekly; during week of study, 4½ days work. House and children are well looked after. Children quite healthy.

Table V.—Weights of Children.

Families having over 8s. per Man per Week.

Family.	M.	F.	Total.	Average age.	Average % of Anthropometric Standard.†					
					Above.		Below.		Above.	Below.

M., male; F., female.

† standard of the Anthropometric Committee's Report, 1883, is accepted as a convenient approximation to the normal.

Father not very strong; gastric condition. The mother suffers from rheumatism; pregnant meanwhile; four children dead.

6. Father, an engine-fitter; at present working half-time. Boy (16) unemployed since January. House is scantily furnished but clean. General condition of children is poor; two suffer from skin disease; child (3) has just recovered from pneumonia and bronchitis. The mother has sores on her face.

7. Father, a hairdresser; unemployed eleven weeks. Family get 10s. food tickets weekly from Lord Provost's Fund. House is well furnished and clean; rent in arrears. General condition of children is quite good; boy (7) has rickets; baby is rather delicate. Father has a bad cough; he was in a Mental Hospital for some time last year.

8. Father, a labourer; only worked two weeks this year and during the past year has been continually unemployed; during this study he got work but was not paid till the following week. Family get two pints free milk daily from the Corporation; five children get dinner in school. A relation lives with them—gives £1 weekly for board. Children quite healthy except baby, who is frequently ill. Mother delicate—rheumatism and anæmia.

9. Father, a steel erector; unemployed since Christmas. Family receive 5s. food tickets weekly from Lord Provost's Fund; 2½ pints free milk daily from the Corporation; five children get dinner in school. The children look healthy, although child (7) has rickets and youngest has whooping-cough. Mother is pregnant.

10. Father, a labourer; unemployed since Christmas; not receiving unemployment benefit. Family have been getting food tickets from the Lord Provost's Fund but none during the week of this study. Mother chars a model lodging-house. House is kept very clean by the father. General condition of the children is fair; child (7) just back from hospital—whooping-cough and pneumonia; baby is very delicate.

11. Father, a carter: unemployed since October; not receiving unemployment benefit. Family gets 5s. food tickets weekly from Lord Provost's Fund. House in a filthy condition; rent in arrears: ejection notice received Father ill—chest trouble. Father and child are ill-nourished.

PUBLIC HEALTH AT CAPE TOWN, 1919-20.[1]

AT the commencement of his annual report for the 12 months ending June 30th, 1920, Dr. A. Jasper Anderson, medical officer of health for the city of Cape Town, expresses a hope that a complete census of the Union of South Africa and its municipalities will be taken during the present year, 1921, and meantime estimates the population of the city at 188,000, of whom 100,000 are Europeans. On this basis the general birth-rate was 35·56 per 1000, compared with 31·86 in 1919, and 35·44 in 1918; and the death-rate 18·87, compared with 45·86 and 20·92 in the two years preceding, the large excess in 1918-19 having been due to the influenza epidemic in October, 1918. If corrected for deaths of persons whose homes were outside the city, the ratio becomes 17·24, compared with 42·38 and 18·69 in the two previous years. The general death-rate for Europeans (12·42) may be compared with that for London in 1919, which was 13·4 per 1000. The infant mortality ratio (which Dr. Anderson states to be the most reliable rate in the report, and "as to some extent a rough index of the sanitary condition of a district") was 145·40 per 1000 births; for European children it was 81·57, for non-Europeans, 183·21; the corresponding ratios (for all classes) in 1919 were 221·37 and in 1918 152·18. There was great variation in the different wards of the city, due, no doubt, to the density of population and sanitary conditions. Thus, among European children, the highest ratio was 113·63 in West Central ward, while in Kalk Bay, Sea Point, and Park wards the ratios were only 30·77, 35·71, and 36·20 respectively. Among non-Europeans in Sea Point the ratio was 85·10, in Park ward it was 113·82, and in every other ward the ratio was higher than this. In five wards the ratio was 200 or over, Salt River being the worst, with 231·21 infantile deaths per 1000 births. The chief causes of this excessive infantile mortality were pneumonia (148 deaths), diseases of the stomach (139), premature birth (123), and bronchitis (106).

The Public Health Act, of June 24th, 1919, came into operation on Jan. 1st, 1920, repealing previous Acts and extending the scope of notification, inspection, &c. There was not a single death from small-pox in the city during the year (only three cases were notified); nor was there any especial zymotic mortality, with the exception of diarrhœa and dysentery (137 deaths), and "enteric and continued fever" (68 deaths). The total zymotic death-rate was 1·55 per 1000, and for Europeans only, 0·78 per 1000. If corrected for deaths of non-residents, these ratios are respectively 1·46 and 0·69, the corresponding ratios for the previous year having been 1·41 and 0·59 per 1000. There were 501 cases of typhoid fever notified, as compared with 444 in the previous year; 283 were Europeans, giving a ratio of 2·83 per 1000 of the population; among non-Europeans this ratio was 2·36. The case-mortality was 9·93 per cent. among Europeans, and 23·7 per cent. among non-Europeans. Salt River ward (96 cases) and Woodstock ward (76 cases) were the wards most affected. Diphtheria was more prevalent than in the previous year (176 cases compared with 145), the disease being introduced from oversea; 139 cases were among Europeans. The death-rate was 0·1 per 1000 for Europeans and 0·14 for non-Europeans, the case-mortality being 9·35 and 32·43 per cent. respectively. Woodstock and East Claremont were the wards chiefly affected. There was also much more scarlet fever in the period under report (308 cases) than during the previous 12 months (179 cases): the type was mild, only four cases having been fatal. Eleven cases of leprosy were notified, of which two were Europeans; the disease was contracted outside the city in all but three cases. There was a slight decrease in tuberculosis notifications (689), as compared with those of the preceding year (709). East Central and Castle wards furnished the largest numbers (112 and 92). It is stated that the only accommodation now available for tuberculous patients consists of ten beds for each sex in the City Hospital, these cases being no longer admitted into the Old Somerset or the General Hospitals. Patients remaining at home are visited fortnightly by the female sanitary inspectors. The need for further hospital accommodation appears to be most urgent. The European death-rate for tuberculosis was 0·9, and for non-Europeans 3·76 per 1000; if corrected for non-resident fatal cases, these ratios become 0·8 and 3·46 respectively; for the population as a whole (all classes) the ratios were 2·21 and 2·01 per 1000. A very important and beneficent work is carried on by a staff of "sanitary inspectresses," under the direction of the medical officer of health. Their chief duties are to advise mothers, investigate deaths of young children, pay fortnightly visits to cases of tuberculosis; also to visit puerperal fever cases, and indigent cases of confinement. A total of 18,651 visits were made during the year under review. Dried milk is supplied for infants who cannot be breast-fed, lactogen having been found to meet requirements in most cases. Amongst other items of interest mentioned in this report, it is noted that the supply of water to the city was restricted from Oct. 29th, 1919, to May 24th, 1920, on account of the reservoirs provided not being large enough to store the quantity of water needed by the inhabitants; also, the rainfall was the lowest recorded for 26 years. A further supply is in course of being provided by the Steenbrass scheme. There are five districts where the pail system is still in force, with only a weekly collection free of charge; but a drainage scheme for these districts "is being rapidly proceeded with." Mosquito prevention and rat extermination are also systematically carried out.

VITAL STATISTICS FOR 1920 OF NON-NATIVE OFFICIALS IN WEST AFRICA.

THIS command report, recently issued by the Colonial Office, shows that a considerable advance towards normal conditions in West Africa has been made during the year under review, and that the staffs generally have been brought up to their full establishment. Over 800 appointments were made in 1920, giving a net increase during the year of 439, and bringing the staff at the end of the year to the highest figure it has ever reached. The death-rate rose from 12·5 in 1919 to 16·3 in 1920—a rise partly due to an exceptional number of deaths from accident (including one death from ptomaine poisoning), or by suicide, these causes accounting for eight out of the total deaths in the year. There remain 36 other deaths due directly to disease, giving a rate of 13·3 per 1000 as against 11·6 per 1000 in 1919. There was one death during the year from malaria, and none from yellow fever. The causes of death during the year were as follows: 11 blackwater fever (accompanied in four cases by uræmia), 2 uræmia, 2 paratyphoid fever, 1 typhoid fever, 3 pneumonia, 1 capillary bronchitis, 3 heart failure, 1 cerebral malaria, 1 dysentery, 1 Bright's disease, 1 arthritis, 1 acute mania, 1 acute meningitis, 1 phthisis, 1 paralysis, 1 purpura variola, 1 gastro-enteritis, 1 acute ulceration of intestine, 1 myocarditis and dilatation of heart, 1 hepatitis, 1 ptomaine poisoning, 3 accidents, 4 suicides. Of these deaths 31 occurred in West Africa, 9 in the United Kingdom, and 4 at sea.

The invaliding rate shows a considerable improvement, having fallen from 27·5 per 1000 in 1919 to 22·7 per 1000.

---

[1] Annual Report of the Medical Officer of Health for year ended June 30th, 1920.

The rate for 1920 is little higher than that for the record years 1916 (22·1 per 1000) and 1917 (20·5 per 1000), and the general downward tendency of the invaliding rate has been well maintained. There were 21 officers pensioned during the year on completing full qualifying service against 15 in 1919, and the number of officials over 52½ years of age at the beginning of 1920 rose to 73 out of a total of 2467, against 59 out of a total of 2305 in 1919 and 48 out of a total of 2631 in 1918. Officers described as "pensioned" have been for not less than seven years in the West African service except in a very few cases of transfer from pensionable appointments elsewhere.

NATIONAL CHILDREN ADOPTION ASSOCIATION.

To the Editor of The Lancet.

Sir,—This Association has for some years carried on its work of promoting the adoption of children and providing homes for children, the circumstances of whose birth appeal to the Association for assistance. The Association's Hostels are at Tower Cressy, Campden Hill, W., Addison House, Holland Park, W., and Southampton. By a recent publication in the press on the subject of 15 children having been sent to America with a view to adoption by a society known as the National Adoption Society much hostile criticism and correspondence has been evoked and has reached our Association through the fact that the correspondents have mistaken the one institution for the other. This confusion has frequently meant unnecessary complication and correspondence.

The National Children Adoption Association has nothing to do with the National Adoption Society, nor does the Association encourage sending children out of this country before the adopting parents have actually seen the children in England and have themselves been interviewed by our Case Committee. Our Association has been criticised because of its supposed action in this matter, especially in view of the fact that the children are stated by the press to have been sent out to America with first-class accommodation, giving the impression that the Association has unlimited funds. That is not the case. The friends of our Association know only too well that, on the contrary, we find it extremely difficult to undertake all the adoption work we could if our income were not so limited.

Possibly we can help to establish the identity of the National Children Adoption Association by stating that our patrons are H.R.H. Princess Alice, Countess of Athlone, and S.A.I. La Princesse Victor Napoleon, and its founder, and now one of its hon. directors, is Miss Clara Andrew.

We are, Sir, yours faithfully,

Mary A. Abercorn,
Dowager Duchess of Abercorn, Chairman of Appeal Committee.
Helen Franklyn,
Lady Franklyn, Chairman of Case Committee.
Beaumont H. Comerford, M.D., D.P.H., M.R.C.S.,
Chairman of Nursing Committee.
Reginald Nicholson, M.P.,
Chairman of Executive Committee.
Gladys Swaythling,
Lady Swathling, President of the Southampton Hostel for Mothers and Babies.

June 21st, 1921.

THE S.A. IMPULSE STARTER FOR MOTOR CARS.

The medical man on a strenuous professional round may well be glad to forgo much of the fatiguing, if healthy, exercise of cranking the engine to start the motor. Most modern cars have a so-called "self-starter" fitted. To adapt one to a car, which is minus this fitting, is rather costly, so an inexpensive compromise, the S.A. Impulse Starter, which has been put on the market by Messrs. Brown Brothers, Ltd., of Great Eastern-street, London, will appeal to those who desire a simple contrivance which amounts almost to a "self-starter." The contrivance in question is a device which fits in the magneto coupling, and gives the armature a sharp initial movement, thereby causing a powerful spark at the exact moment required when starting the engine. By pulling a pawl into engagement with the armature plate attached to the armature spindle the magneto armature is temporarily arrested, and a spiral spring inside the starter is wound up. The energy thus stored up, when the cam on the cam casing disengages the pawl, causes a rapid impulse to the magneto armature, equivalent to revolving it at the rate of 500 revolutions per minute. Thus an intense spark at the plug in the cylinder which is on the firing stroke is provided. If the engine has been primed by squirting a little petrol or startol [illegible] cylinders previously, the engine immediately starts. [illegible] it start without the priming, but it is as well to make [illegible] applying the dope. Directly the engine revolves under its own power the pawl is thrown out of operation and the design is such that it is impossible for the Impulse Starter to come into operation after the engine is running. It can be easily fitted to any car that has magneto ignition.

A NEW RIMLESS PINCE-NEZ.

Twenty years ago Messrs. Frederick Bateman and Co. submitted to us the Usebius pince-nez frame, in which any disagreeable pinching effect upon the nose was avoided by the device of a stop nut on a screw thread arranged to take part of the tension of the spring. The same firm has now sent us a specimen of their new Winner mount, which is exceedingly light in weight and appearance, and embodies a further improvement. The nose-piece contains a hidden spring which, whenever the ordinary tension is relaxed, emerges from its cell and adds just sufficient grip to prevent the glasses falling off under unusual conditions. They are especially suitable for work where the head is in rapid movement or held out of the vertical line. We have tried the mount which is comfortable and gives a feeling of security. The head office of the maker is 55, Berners-street, London, W. 1.

THE CHEMISTS' EXHIBITION.

This exhibition, the twenty-second of its kind, was held from June 20th to 24th, at the Central Hall, Westminster. The general arrangements were highly creditable to the *British and Colonial Pharmacist*, the proprietors of which are the organisers. Primarily, the exhibition was intended for pharmacists and others associated with the retailing of pharmaceutical goods, but nevertheless it was full of interest to the general public. Most of the well-known manufacturers of fine chemicals exhibited, and it is gratifying to be able to record that many of the products displayed have only recently been successfully manufactured in England. Among these aspirin, thymol, vanillin, benzyl benzoate, citronellol, and others were noticed. Sundries such as perfumes, sponges, brushes, soaps, and surgical dressings formed an important part of the exhibition.

AN IMPROVED RUBBER SHEETING.

We have received from Messrs. Louis Minton, of Trevelyan Buildings, Manchester, specimens of their red and white rubber waterproof sheeting. This fabric, which has received the name of "Minite," is prepared by mixing the rubber with powdered mica, the same mineral being used as a surface finish. On trial we find that acids and heat have little or no effect upon the material, which, we are assured by the manufacturers, does not crack after prolonged use. The process is applicable to many rubber productions, including jaconet, and surgical appliances where surface protection is necessary.

A THIMBLE TOOTH-BRUSH.

Mr. W. S. Benson, of 53, Lord-street, Liverpool, has sent us samples of a hygienic tooth-brush which he has designed and called the Wedge-rub. It consists of an indiarubber thimble to be worn on the finger which it best fits. Tooth-paste or powder is applied on the roughened surface of the thimble, which is then rubbed up and down on the teeth and gums. A thin rubber wedge on the thimble is intended to clean the intervals between the teeth. The inventor claims the following advantages for his device: cleanliness, no bristles to become loose, suitability for tender gums, durability, and portability. Certainly a couple of these thimbles might conveniently be put in the sponge-bag for a journey.

Lumleian Lectures

ON

SOME POINTS IN THE ÆTIOLOGY OF SKIN DISEASES.

Delivered before the Royal College of Physicians of London on March 10th, 15th, and 17th, 1921,

By ARTHUR WHITFIELD, M.D., F.R.C.P. Lond.,
PHYSICIAN IN CHARGE, SKIN DEPARTMENT, KING'S COLLEGE HOSPITAL.

LECTURE I.*

The study of disease as it affects the skin is by no means without interest and importance, but depending, as it often does, on minute clinical signs and intricate histological changes it is a subject which appears to me to offer great difficulty to the lecturer in his endeavour to produce an interesting discourse. I think it will be admitted by most physicians that dermatology has been in some respects the Cinderella of the special medical studies, and that while neurology, and more recently cardiology, have held honoured places as subdivisions of the great study of general medicine, dermatology has been viewed with a certain degree of contempt.

The cause of this is, perhaps, not far to seek. Whereas neurology and cardiology in their earliest infancy were connected with much patient and brilliant pathological research, dermatology was unfortunately hampered in its youth by a cumbrous and fanciful pseudo-botanical nomenclature, and the earlier research work was, perhaps, too exclusively devoted to histological details, some of which may have been, like the already mentioned nomenclature, fanciful and without good foundation.

I believe that these errors are now passing away, and that a more rational method of study is developing; that less close attention is being devoted to peculiar efflorescences and distribution, and certainly less to the invention of hybrid classical names, and that greater effort is being expended on the elucidation of the ætiology and pathology of the cutaneous abnormalities with which we have been long familiar. Since this change has been instrumental in bringing dermatology into closer relationship to general medicine as a whole, and as it is my hope to attempt to offer you a discourse not entirely without interest to the general physician, I have chosen this matter of ætiology as the subject of my lectures.

It was at first my intention to deal with the internal factors only, as being of greater general medical interest. On further consideration, however, I came to the conclusion that there existed points of interest to the physician in certain cases of almost exclusively local ætiology. I therefore decided to include some discussion of the external factors as well.

Perhaps it is necessary to state that I claim no originality for the work I intend to review; some of it has been published for some time, some of it is still in a more or less inchoate state, and much of it has been suggested to me by friends and colleagues in informal interchange of views.

When we attempt to separate the external from the internal factors in ætiology we are met at once with a good deal of difficulty. These two factors are frequently inseparable, and even in cases where the condition seems to be due very obviously to one or other alone careful observation may sometimes show that a combination is at work after all.

In support of this contention I would mention two types of skin condition.

Effect of Constitutional Condition on Diseases Due to Local Irritation.

The first is that of occupational dermatitis, where apparently we have to deal with the action of a local irritant pure and simple; yet further investigation has shown that in some forms at least of so-called professional dermatitis a strong internal ætiological factor is present. Jacquet and Jourdanet[1] found that of 29 cases of professional dermatitis they were able to cure or improve 14 cases by dieting, local treatment, and removal from work, 4 cases by dieting and removal from work without local treatment, and 9 cases by dieting without local treatment or cessation of work, while in the two failures it was found that the treatment had not been carried out. If I may be allowed to criticise this paper, I would suggest that in that group which recovered without in any way interfering with the professional occupation, it is at least open to doubt whether the disease could fairly be called professional dermatitis.

Effect of Local Stimulant on Diseases of Internal Origin.

The second condition that I would mention is the eruption produced by the ingestion of bromides. In this case we have a condition that is apparently due almost purely to the noxious influence of the ingested drug, and further it is, I think, common knowledge that where there is insufficiency of the renal function the eruption may be called forth by smaller doses. Yet even here there is or may be a local factor at work.

Some years ago I reported a case of bromide eruption on the face of a young infant occurring on the third day after birth. This was apparently due to absorption of bromide in utero, since the mother, who had taken large doses during pregnancy, never had any milk, and the baby was given no drugs at any time. Here we see what is probably the influence of light, as the eruption was not present at birth, and when it appeared did so on the face.

A second instance of the same eruption, but with a different local ætiology, may also be of interest. This was the case of an epileptic male, 38 years of age, who had taken bromide in large quantities since early youth. He suffered from time to time from small acneiform lesions, but nothing to cause any great inconvenience. A few years before he came to me he had a fall from his bicycle and grazed his left shin severely and his right one slightly. The wounds healed slowly, and as soon as he reached his usual dose of bromide the damaged areas became the seats of a typical bromide eruption of the tuberous type. He was sent to me to see if I could help him while he continued the drug, but everything I tried was quite valueless.

These two cases led me to ponder over the localisation of the bromide eruption of the tuberous type, and I suggest that this depends very largely on local irritation. The commonest sites are, I think, the face, the buttocks in children, and the tibial regions in older people. I believe the localisation on the face to be due to exposure to light, that on the buttocks and thighs of infants to irritation by the wet napkin, and possibly also to friction by scrubbing along on the floor, and that the shins of older people are attacked because they are so frequently the site of mechanical injury.

In connexion with the bromide eruptions I may describe a case[2] in which the occurrence of the bromide lesion determined the site of a syphilitic eruption. The patient was a young woman who was sent to my out-patient department with some tuberous papules on the upper lip and chin. On examination these showed the typical miliary pustules lying in dome-shaped nodes. The diagnosis of bromide eruption was offered and inquiry was made of the doctor as to whether he had given the drug. He replied that he had given bromide of potassium for a fortnight for the treatment of severe headache. The drug was discontinued and the patient kept under observation, and in a fortnight the eruption was in full retrogression. A week or so later, however, the infiltration seemed to be returning although no more of the drug had been ingested. On close examination it was observed that the character of the nodules was changing. They no longer showed the pinhead pustules: they were much darker in colour and tougher and less succulent in consistence. In fact, they now suggested the diagnosis of papular syphilis, and as no further clinical evidence was forthcoming beyond the somewhat persistent and severe headache, the blood was examined and found to give a strongly positive Wassermann reaction. The patient was accordingly treated with arsenobenzol injections and mercury, and all the symptoms cleared up rapidly.

---

* Lectures II. and III. will appear in subsequent issues of The Lancet.

In this case, therefore, we have apparently an instance of the damage to the tissues by bromide determining the localisation of the syphilide. It is regrettable that we could not ascertain definitely the stage of the syphilis. I was inclined to believe from the severe headache and general toxæmia that the infection was early, but I felt it was unjustifiable to delay treatment in order to allow further secondary symptoms to develop and prove the position, as I considered it would be detrimental to the patient's future.

Such a case as the above appears to me to have an added interest for the reason that it sets a trap for the unwary. Having once established a firm diagnosis one is naturally apt to rest content, but this is not really justifiable in any case where the course of the eruption takes an unexpected turn. One should, I think, be prepared to review one's original diagnosis in the light of any fresh evidence that may develop and although I am not attempting in these lectures to present to you any of the extremely fine details upon which we rely to make our diagnosis, I may be permitted to point out that it is only by the acquisition of minute powers of observation that the all-important diagnosis can be made, and often in such a way that the ætiology may be suspected.

PROBLEMS OF INFLAMMATORY DERMATITIS.

I may now turn to some of the more puzzling forms of inflammatory dermatitis, which strain to the utmost the capacity of the dermatologist who attempts to make an ætiological diagnosis. We are met here at once by a wrangle about nomenclature to which I should like to avoid referring, as I have already expressed my disapproval of the undue importance which has been attributed to names and classification in the past. Nevertheless one must have a label for a set of clinical symptoms, and this label should be intelligible to other workers.

The dispute to which I refer is about the term "eczema." Willan and Bateman applied it to an eruption chiefly of external origin, eczema solare, &c. They did, however—and this was a great merit—define exactly the clinical lesion to which they applied the term, and they pointed out that the essential lesion was a small tense vesicle which formed aggregations. Later the French authors laid stress on the diathetic causation of the eruption, and later still Hebra returned more or less to the Willan-Bateman ideas. Up to this point the disease was considered to be a non-infective dermatitis.

After this Unna took up the subject, and in my opinion set dermatology on the wrong track by an inaccuracy of clinical observation. He described the essential lesion as to all intents and purposes a flaccid bulla or pustule, and sought to prove that it was due to an infection with a pyogenic organisation that he named the morococcus. This infective theory had a considerable vogue, and Leredde of Paris wrote a monograph on it entitled "Eczema: Maladie Parasitaire." Unna, in spite of his immense amount of work, unintentionally did, in my opinion, great disservice to dermatology by his theories, and although they have largely lost favour the echo of them still remains here and there.

From all this arose the question: "To what are we to attach the name of eczema?" Henceforward the dermatological world became divided roughly into two camps—namely, those who, relying on the type [illegible]n present, classed all eruptions of a certain [illegible] form as eczema, and those who wished to exclude from the category all those eruptions in which an external irritant could be found to be the cause. This latter group, however, required a label for the syndrome and they called it dermatitis.

I confess myself an unrepentant adherent of the older Willan-Bateman school. It appears to me that eczema is rather a type of reaction than a disease, and that the name is still a useful label for a certain clinical type of eruption. To call it dermatitis is only to transfer the difficulty to another label which does not connote in a familiar manner a certain group of symptoms. I shall therefore assume that by eczema we mean an eruption of pinhead-sized œdematous papules which may or may not go on to the formation of macroscopic vesicles, such papules not showing well-marked intrinsic enlargement but rather running together to form sheets, in some cases disappearing in the centre of the patch and spreading at the edge so that rings and polycyclical figures are formed. The papules may be follicular in site, or may occur on the glabrous portions of the skin. They may form very acutely, in which case the serous exudation and hyperæmia are the most marked features, or, if the inflammation is of lower intensity and more chronic nature, hyperkeratosis and scaling are more in evidence.

The frequency of eruptions of this type is such that if we can elucidate their ætiology and thereby arrive at an efficient method of treatment we shall be in a position to deal satisfactorily with the majority of the skin diseases met with in general and special practice.

I have been guilty of attempting to define eczema in a more or less ætiological manner in the following terms:—

Eczema is an acute or chronic eruption of pinhead-sized œdematous papules and vesicles due to an exalted susceptibility of the skin, either congenital or acquired, to the action of external irritants. In attempting to form a conception of the ætiology of these eruptions I have been greatly aided by the work of Prof. Jadassohn[3] on the external factor.

SUSCEPTIBILITY AND IDIOSYNCRASY TO EXTERNAL AGENCIES.

If we take a large number of individuals we shall find that we can divide them roughly into three groups. The first and much the largest group will show roughly the same reaction to common irritants such as chemical and physical agencies. Such a reaction may therefore be called the normal susceptibility of the skin. A second, and for our purpose less important group, will show a resistance much greater than normal, and these people need not delay us since they do not as a rule suffer from eczema at all. The third and most important group show an unusual susceptibility to one or more irritants, and these may be said to have an undue susceptibility of the skin to agencies which are irritants to most people. This last group may again be subdivided into those who show a susceptibility to one agency and those who show it to most irritants. Accordingly we may say that they show a "special" or a "general" susceptibility. Unless a certain heightening of this susceptibility has taken place from repeated action of the irritant it is largely a matter of dosage in these cases, and this is an important point, because there is another class of patient who reacts in a way which appears to be different.

There is a number of substances which are to the average person not irritants at all in any ordinary dosage. Yet there are individuals who react very violently to these bodies in doses which are so small that dosage may be said generally to be unimportant. As a good instance of this one may take iodoform. Most people can handle iodoform without evil result, yet there are people in whom contact with a small crystal will call forth the most intense inflammatory eruption, sometimes eczematous in type and sometimes so bullous that I have seen it mistaken for pemphigus. Such people may be said to have an idiosyncrasy to the agency in question.

So far I have followed the teaching of Jadassohn pretty closely, but I would now point out that although this classification into special and general susceptibility and idiosyncrasy has elements of truth in it sufficient to make it of practical use, yet too much weight must not be laid on it or it will break down. One of the points of difference laid down between susceptibility and idiosyncrasy is the fact that in idiosyncrasy the agency does not affect the average person at all, and a second is that dosage is hardly important, as I have already stated. But if we take a number of the agencies in connexion with which an idiosyncrasy is assumed we can build up a pyramid of which the base will be formed of those to which idiosyncrasy is common and the apex of those to which it is rare. Again, if we take an individual whose susceptibility has been artificially raised by frequent exposure we may find that dosage is practically as small as that in idiosyncrasy. We may therefore trace an almost continuous series between susceptibility and idiosyncrasy. It will, perhaps, be well to give instances relating to these points.

First as regards the relative frequency of idiosyncrasy to any one poison. As example I would quote the poison of *Rhus toxicodendron* (American "Poison ivy"), and that of *Primula obconica*. Both of these plants cause irritant dermatitis in so large a number of people, though in what proportion of the population I cannot say, that they are well known as general causes of eczema.

Nevertheless, where insusceptibility exists it seems to be almost absolute, and I have a clear instance of this in a distinguished horticulturist who suffered severely from eczema chiefly of internal origin. This patient told me that, though a martyr to eczema in some ways, he could handle both *Rhus toxicodendron* and *Primula obconica* with impunity.

Secondly as regards the minute dosage required with common irritants in a sensitised patient. Formic aldehyde is a good example of a common irritant, and I know of one patient who after several attacks became so sensitive that if he went into a well-ventilated room in which the chemical had been used some hours before he broke out in an eczematous rash in a few hours.

There is perhaps this point of difference between the two varieties—namely, the condition of the general health and the skin in relationship to outbreaks. I have already pointed out that Jacquet and Jourdanet have found the constitutional condition to have a very distinct influence on professional dermatitis, and I have also mentioned that the horticultural amateur, though actually a sufferer from eczema, found that the idiosyncratic poisons had no influence on the eruption.

In this matter of idiosyncrasy the efficient cause ay be sufficiently obvious, or, on the other hand, ay be extremely elusive. Even with the well-known ases the inexpert may be deceived, as patients mislead unintentionally in the narration of their owing to preconceived ideas as to the ætiology eir trouble.

following is a good instance of this type of

was sent to me suffering from severe eczema of the ace, and chest of about eight months' duration. Her was that she was greatly depressed in health partly nancial worry and partly from overwork in the of her home. Shortly before the outbreak of attack she had moved into another house. This, entailed an enormous amount of work, as she did cleaning of the new abode herself. The scrubbing tired her out and made her feel more ill than this culminated in her breaking down with an of eczema from which she had never quite was the history that she gave me when she room.

examination I came to the conclusion that with an eczema of external origin. I thereed her as to the plants in the garden, and that there was only some lilacs and ferns. ed my attention to wall-papers, carpets, but drew blank in every direction. I remembered that under the heading of plants ly mentioned climbers, so I harked back to this. I then learned that there was a "sort of virginia creeper" on the house. It was then winter and the plant was leafless, but I got the patient to send up a branch to Kew for identification, and to my satisfaction the report came back—*Rhus toxicodendron*. This plant, though very well known as a common weed in the United States, is so uncommon in England that people are ignorant of its evil properties. I have only come across two cases of poisoning by it in England, though I believe there is a fair number of plants scattered over the country under the name of *Ampelopsis Hoggii*. At all events, when the cause was once elucidated, the eruption was immediately seen to have a very obvious ætiology, the climber was destroyed, and no further attacks occurred.

Such cases seem simple enough when the ætiology is once elucidated, but much time and trouble is needed in many cases before the offending poison is identified. One point which causes difficulty is the almost incredibly small dose of the idiosyncratic poison which is necessary to produce severe symptoms. It must be remembered, also, that although there is a large number of bodies the qualities of which are well established, there are almost certainly many others which still remain undetected. It is scarcely to be wondered at, therefore, that on occasions the presence of an external intoxication cannot be established, although it may be suspected. As examples of the minute dosage required I may, perhaps, quote two cases.

The first is that of a child, reported by the late Prof. James White[4] in his book on dermatitis venenata. This child, aged 6 years, was twice poisoned one summer with *Rhus toxicodendron*. Consequently the next year a boy who was known to be insusceptible was employed to tea up all the plants growing near the house. This boy was the made to wash his hands, first in hot water with soap an subsequently with vinegar. As a precaution, in spite o his supposed insusceptibility, he was watched during th process by the mother of the susceptible child. In the afte noon this boy took the susceptible child to a pond to bath Having stripped him he took him into the water, holdi him by the armpits and afterwards rubbing his back wi his open palms. Two or three days later the child was tak ill and grew rapidly worse. Deep ulcers appeared under t armpits and the skin of his back exhibited in an aggravat form the usual marks of poisoning by "ivy." He di the end of the third week of his illness.

The second case to which I will allude is published by Dr Arthur Hall[5] some years ago.

The patient was demonstrator in a chemical labor In July, 1891, he began to suffer slightly from ecze his fingers. This disappeared on his vacation, but reapp on his return in September. He was at this time en in a research necessitating the use of phenylhydrazi benzaldehyde. He gave this up for a time, but at E 1895, he returned to it, and during one of his experi noticed that a good deal of vapour was given off. The evening he developed an attack of acute eczema on the neck, ears, and scrotum. This slowly died away. repeating his experiments he developed a fresh attack December, 1895, he upset some phenylhydrazin on his and in two hours developed widespread attack. He gave up experimenting with phenylhydrazin. He wa from December, 1895, to November, 1898, and then fresh attack and found that a student was using the ch in the laboratory.

He was again free until July, 1898, when he assistant to do some experiments with it in a roo directly connected with the laboratory. The assistan and talked with him for a few minutes and another resulted. Finally, while convalescing at home fro attack his assistant came to talk with him after a mile through the open air, and he immediately de a relapse.

I now quote a case of the elusive variety.

A lady was sent to me for recurrent attacks of e the hands and face. Her story was that she had fa but was very "gouty," and about a year previo had an attack of "gouty eczema." This had been s resistant, so she was sent to Harrogate where she rapidly. A recurrence took place, and again she at Harrogate. Since then more recurrences h place at short intervals. The type of eruption su me an eczema due to external toxin. Close q revealed the fact that while on a visit to friends the patient was free from trouble, and that on away from home she was also free. This she ex the rather relaxing climate where her country hous ated. I then inquired for plants, f niture, wall p was changing. They no longer showed the pinhead pustules; they were much darker in colour and tougher and less succulent in consistence. In fact, they now suggested the diagnosis of papular syphilis, and as no further clinical evidence was forthcoming beyond the somewhat persistent and severe headache, the blood was examined and found to give a strongly positive Wassermann reaction. The patient was accordingly treated with arsenobenzol injections and mercury, and all the symptoms cleared up rapidly.

In this case, therefore, we have apparently an instance of the damage to the tissues by bromide determining the localisation of the syphilide. It is regrettable that we could not ascertain definitely the stage of the syphilis. I was inclined to believe from the severe headache and general toxæmia that the infection was early, but I felt it was unjustifiable to delay treatment in order to allow further secondary symptoms to develop and prove the position, as I considered it would be detrimental to the patient's future.

Such a case as the above appears to me to have an added interest for the reason that it sets a trap for the unwary. Having once established a firm diagnosis one is naturally apt to rest content, but this is not really justifiable in any case where the course of the eruption takes an unexpected turn. One should, I think, be prepared to review one's original diagnosis in the light of any fresh evidence that may develop and although I am not attempting in these lectures to present to you any of the extremely fine details upon which we rely to make our diagnosis, I may be permitted to point out that it is only by the acquisition of minute powers of observation that the all-important diagnosis can be made, and often in such a way that the ætiology may be suspected.

PROBLEMS OF INFLAMMATORY DERMATITIS.

I may now turn to some of the more puzzling forms of inflammatory dermatitis, which strain to the utmost the capacity of the dermatologist who attempts to make an ætiological diagnosis. We are met here at once by a wrangle about nomenclature to which I should like to avoid referring, as I have already expressed my disapproval of the undue importance which has been attributed to names and classification in the past. Nevertheless one must have a label for a set of clinical symptoms, and this label should be intelligible to other workers.

The dispute to which I refer is about the term "eczema." Willan and Bateman applied it to an eruption chiefly of external origin, eczema solare, &c. This patient told me that, though a martyr to eczema in some ways, he could handle both *Rhus toxicodendron* and *Primula obconica* with impunity.

Secondly as regards the minute dosage required with common irritants in a sensitised patient. Formic aldehyde is a good example of a common irritant, and I know of one patient who after several attacks became so sensitive that if he went into a well-ventilated room in which the chemical had been used some hours before he broke out in an eczematous rash in a few hours.

There is perhaps this point of difference between the two varieties—namely, the condition of the general health and the skin in relationship to outbreaks. I have already pointed out that Jacquet and Jourdanet have found the constitutional condition to have a very distinct influence on professional dermatitis, and I have also mentioned that the horticultural amateur, though actually a sufferer from eczema, found that the idiosyncratic poisons had no influence on the eruption.

In this matter of idiosyncrasy the efficient cause may be sufficiently obvious, or, on the other hand, may be extremely elusive. Even with the well-known causes the inexpert may be deceived, as patients often mislead unintentionally in the narration of their histories owing to preconceived ideas as to the ætiology of their trouble.

The following is a good instance of this type of history.

A lady was sent to me suffering from severe eczema of the arms, face, and chest of about eight months' duration. Her history was that she was greatly depressed in health partly from financial worry and partly from overwork in the management of her home. Shortly before the outbreak of her first attack she had moved into another house. This, of course, entailed an enormous amount of work, as she did much of the cleaning of the new abode herself. The scrubbing and labour tired her out and made her feel more ill than before, and this culminated in her breaking down with an acute attack of eczema from which she had never quite recovered. Such was the history that she gave me when she came into my room.

On careful examination I came to the conclusion that we had to do with an eczema of external origin. I therefore questioned her as to the plants in the garden, and was informed that there was only some lilacs and ferns. I therefore directed my attention to wall-papers, carpets, and furniture, but drew blank in every direction. I then suddenly remembered that under the heading of plants I had not specifically mentioned climbers, so I harked back to this. I then learned that there was a "sort of virginia creeper" on the house. It was then winter and the plant was leafless, but I got the patient to send up a branch to Kew for identification, and to my satisfaction the report came back—*Rhus toxicodendron*. This plant, though very well known as a common weed in the United States, is so uncommon in England that people are ignorant of its evil properties. I have only come across two cases of poisoning by it in England, though I believe there is a fair number of plants scattered over the country under the name of *Ampelopsis Hoggii*. At all events, when the cause was once elucidated, the eruption was immediately seen to have a very obvious ætiology, the climber was destroyed, and no further attacks occurred.

Such cases seem simple enough when the ætiology is once elucidated, but much time and trouble is needed in many cases before the offending poison is identified. One point which causes difficulty is the almost incredibly small dose of the idiosyncratic poison which is necessary to produce severe symptoms. It must be remembered, also, that although there is a large number of bodies the qualities of which are well established, there are almost certainly many others which still remain undetected. It is scarcely to be wondered at, therefore, that on occasions the presence of an external intoxication cannot be established, although it may be suspected. As examples of the minute dosage required I may, perhaps, quote two cases.

The first is that of a child, reported by the late Prof. James White[4] in his book on dermatitis venenata. This child, aged 6 years, was twice poisoned one summer with *Rhus toxicodendron*. Consequently the next year a boy who was known to be insusceptible was employed to tear up all the plants growing near the house. This boy was then made to wash his hands, first in hot water with soap and subsequently with vinegar. As a precaution, in spite of his supposed insusceptibility, he was watched during this process by the mother of the susceptible child. In the afternoon this boy took the susceptible child to a pond to bathe. Having stripped him he took him into the water, holding him by the armpits and afterwards rubbing his back with his open palms. Two or three days later the child was taken ill and grew rapidly worse. Deep ulcers appeared under the armpits and the skin of his back exhibited in an aggravated form the usual marks of poisoning by "ivy." He died at the end of the third week of his illness.

The second case to which I will allude is that published by Dr Arthur Hall[5] some years ago.

The patient was demonstrator in a chemical laboratory. In July, 1891, he began to suffer slightly from eczema on his fingers. This disappeared on his vacation, but reappeared on his return in September. He was at this time engaged in a research necessitating the use of phenylhydrazin and benzaldehyde. He gave this up for a time, but at Easter, 1895, he returned to it, and during one of his experiments noticed that a good deal of vapour was given off. The same evening he developed an attack of acute eczema on the face, neck, ears, and scrotum. This slowly died away. On repeating his experiments he developed a fresh attack. In December, 1895, he upset some phenylhydrazin on his hand, and in two hours developed widespread attack. He then gave up experimenting with phenylhydrazin. He was free from December, 1895, to November, 1896, and then had a fresh attack and found that a student was using the chemical in the laboratory.

He was again free until July, 1898, when he got an assistant to do some experiments with it in a room not directly connected with the laboratory. The assistant came and talked with him for a few minutes and another attack resulted. Finally, while convalescing at home from this attack his assistant came to talk with him after walking a mile through the open air, and he immediately developed a relapse.

I now quote a case of the elusive variety.

A lady was sent to me for recurrent attacks of eczema of the hands and face. Her story was that she had fair health, but was very "gouty," and about a year previously had had an attack of "gouty eczema." This had been somewhat resistant, so she was sent to Harrogate where she was cured rapidly. A recurrence took place, and again she was cured at Harrogate. Since then more recurrences had taken place at short intervals. The type of eruption suggested to me an eczema due to external toxin. Close questioning revealed the fact that while on a visit to friends in London the patient was free from trouble, and that on any visit away from home she was also free. This she explained by the rather relaxing climate where her country house was situated. I then inquired for plants, furniture, wall papers, &c.,

was changing. They no longer showed the pinhead pustules; they were much darker in colour and tougher and less succulent in consistence. In fact, they now suggested the diagnosis of papular syphilis, and as no further clinical evidence was forthcoming beyond the somewhat persistent and severe headache, the blood was examined and found to give a strongly positive Wassermann reaction. The patient was accordingly treated with arsenobenzol injections and mercury, and all the symptoms cleared up rapidly.

In this case, therefore, we have apparently an instance of the damage to the tissues by bromide determining the localisation of the syphilide. It is regrettable that we could not ascertain definitely the stage of the syphilis. I was inclined to believe from the severe headache and general toxæmia that the infection was early, but I felt it was unjustifiable to delay treatment in order to allow further secondary symptoms to develop and prove the position, as I considered it would be detrimental to the patient's future.

Such a case as the above appears to me to have an added interest for the reason that it sets a trap for the unwary. Having once established a firm diagnosis one is naturally apt to rest content, but this is not really justifiable in any case where the course of the eruption takes an unexpected turn. One should, I think, be prepared to review one's original diagnosis in the light of any fresh evidence that may develop and although I am not attempting in these lectures to present to you any of the extremely fine details upon which we rely to make our diagnosis, I may be permitted to point out that it is only by the acquisition of minute powers of observation that the all-important diagnosis can be made, and often in such a way that the ætiology may be suspected.

PROBLEMS OF INFLAMMATORY DERMATITIS.

I may now turn to some of the more puzzling forms of inflammatory dermatitis, which strain to the utmost the capacity of the dermatologist who attempts to make an ætiological diagnosis. We are met here at once by a wrangle about nomenclature to which I should like to avoid referring, as I have already expressed my disapproval of the undue importance which has been attributed to names and classification in the past. Nevertheless one must have a label for a set of clinical symptoms, and this label should be intelligible to other workers.

The dispute to which I refer is about the term "eczema." Willan and Bateman applied it to an eruption chiefly of external origin, eczema solare, &c. They did, however—and this was a great merit—define exactly the clinical lesion to which they applied the term, and they pointed out that the essential lesion was a small tense vesicle which formed aggregations. Later the French authors laid stress on the diathetic causation of the eruption, and later still Hebra returned more or less to the Willan-Bateman ideas. Up to this point the disease was considered to be a non-infective dermatitis.

After this Unna took up the subject, and in my opinion set dermatology on the wrong track by an inaccuracy of clinical observation. He described the essential lesion as to all intents and purposes a flaccid bulla or pustule, and sought to prove that it was due to an infection with a pyogenic organisation that he named the morococcus. This infective theory had a considerable vogue, and Leredde of Paris wrote a monograph on it entitled "Eczema: Maladie sitaire." Unna, in spite of his immense amount ork, unintentionally did, in my opinion, great rvice to dermatology by his theories, and although y have largely lost favour the echo of them still ains here and there.

From all this arose the question: "To what are we to attach the name of eczema?" Henceforward the dermatological world became divided roughly into two camps—namely, those who, relying on the type of lesion present, classed all eruptions of a certain clinical form as eczema, and those who wished to exclude from the category all those eruptions in which an external irritant could be found to be the cause. This latter group, however, required a label for the syndrome and they called it dermatitis.

I confess myself an unrepentant adherent of the older Willan-Bateman school. It appears to me that eczema is rather a type of reaction than a disease, and that the name is still a useful label for a certain clinical type of eruption. To call it dermatitis is only to transfer the difficulty to another label which does not connote in a familiar manner a certain group of symptoms. I shall therefore assume that by eczema we mean an eruption of pinhead-sized œdematous papules which may or may not go on to the formation of macroscopic vesicles, such papules not showing well-marked intrinsic enlargement but rather running together to form sheets, in some cases disappearing in the centre of the patch and spreading at the edge so that rings and polycyclical figures are formed. The papules may be follicular in site, or may occur on the glabrous portions of the skin. They may form very acutely, in which case the serous exudation and hyperæmia are the most marked features, or, if the inflammation is of lower intensity and more chronic nature, hyperkeratosis and scaling are more in evidence.

The frequency of eruptions of this type is such that if we can elucidate their ætiology and thereby arrive at an efficient method of treatment we shall be in a position to deal satisfactorily with the majority of the skin diseases met with in general and special practice.

I have been guilty of attempting to define eczema in a more or less ætiological manner in the following terms:—

Eczema is an acute or chronic eruption of pinhead-sized œdematous papules and vesicles due to an exalted susceptibility of the skin, either congenital or acquired, to the action of external irritants. In attempting to form a conception of the ætiology of these eruptions I have been greatly aided by the work of Prof. Jadassohn[3] on the external factor.

SUSCEPTIBILITY AND IDIOSYNCRASY TO EXTERNAL AGENCIES.

If we take a large number of individuals we shall find that we can divide them roughly into three groups. The first and much the largest group will show roughly the same reaction to common irritants such as chemical and physical agencies. Such a reaction may therefore be called the normal susceptibility of the skin. A second, and for our purpose less important group, will show a resistance much greater than normal, and these people need not delay us since they do not as a rule suffer from eczema at all. The third and most important group show an unusual susceptibility to one or more irritants, and these may be said to have an undue susceptibility of the skin to agencies which are irritants to most people. This last group may again be subdivided into those who show a susceptibility to one agency and those who show it to most irritants. Accordingly we may say that they show a "special" or a "general" susceptibility. Unless a certain heightening of this susceptibility has taken place from repeated action of the irritant it is largely a matter of dosage in these cases, and this is an important point, because there is another class of patient who reacts in a way which appears to be different.

There is a number of substances which are to the average person not irritants at all in any ordinary dosage. Yet there are individuals who react very violently to these bodies in doses which are so small that dosage may be said generally to be unimportant. As a good instance of this one may take iodoform. Most people can handle iodoform without evil result, yet there are people in whom contact with a small crystal will call forth the most intense inflammatory eruption, sometimes eczematous in type and sometimes so bullous that I have seen it mistaken for pemphigus. Such people may be said to have an idiosyncrasy to the agency in question.

So far I have followed the teaching of Jadassohn pretty closely, but I would now point out that although this classification into special and general susceptibility and idiosyncrasy has elements of truth in it sufficient to make it of practical use, yet too much weight must not be laid on it or it will break down. One of the points of difference laid down between susceptibility and idiosyncrasy is the fact that in idiosyncrasy the agency does not affect the average person at all, and a second is that dosage is hardly important, as I have already stated. But if we take a number of the agencies in connexion with which an idiosyncrasy is assumed we can build up a pyramid of which the base will be formed of those to which idiosyncrasy is common and the apex of those to which it is rare. Again, if we take an individual whose susceptibility has been artificially raised by frequent exposure we may find that dosage is practically as small as that in idiosyncrasy. We may therefore trace an almost continuous series between susceptibility and idiosyncrasy. It will, perhaps, be well to give instances relating to these points.

First as regards the relative frequency of idiosyncrasy to any one poison. As example I would quote the poison of *Rhus toxicodendron* (American "Poison ivy"), and that of *Primula obconica*. Both of these plants cause irritant dermatitis in so large a number of people, though in what proportion of the population I cannot say, that they are well known as general causes of eczema.

Nevertheless, where insusceptibility exists it seems to be almost absolute, and I have a clear instance of this in a distinguished horticulturist, who suffered severely from eczema chiefly of internal origin. This patient told me that, though a martyr to eczema in some ways, he could handle both *Rhus toxicodendron* and *Primula obconica* with impunity.

Secondly as regards the minute dosage required with common irritants in a sensitised patient. Formic aldehyde is a good example of a common irritant, and I know of one patient who after several attacks became so sensitive that if he went into a well-ventilated room in which the chemical had been used some hours before he broke out in an eczematous rash in a few hours.

There is perhaps this point of difference between the two varieties—namely, the condition of the general health and the skin in relationship to outbreaks. I have already pointed out that Jacquet and Jourdanet have found the constitutional condition to have a very distinct influence on professional dermatitis, and I have also mentioned that the horticultural amateur, though actually a sufferer from eczema, found that the idiosyncratic poisons had no influence on the eruption.

In this matter of idiosyncrasy the efficient cause may be sufficiently obvious, or, on the other hand, may be extremely elusive. Even with the well-known causes the inexpert may be deceived, as patients often mislead unintentionally in the narration of their histories owing to preconceived ideas as to the ætiology of their trouble.

The following is a good instance of this type of history.

A lady was sent to me suffering from severe eczema of the arms, face, and chest of about eight months' duration. Her history was that she was greatly depressed in health partly from financial worry and partly from overwork in the management of her home. Shortly before the outbreak of her first attack she had moved into another house. This, of course, entailed an enormous amount of work, as she did much of the cleaning of the new abode herself. The scrubbing and labour tired her out and made her feel more ill than before, and this culminated in her breaking down with an acute attack of eczema from which she had never quite recovered. Such was the history that she gave me when she came into my room.

On careful examination I came to the conclusion that we had to do with an eczema of external origin. I therefore questioned her as to the plants in the garden, and was informed that there was only some lilacs and ferns. I therefore directed my attention to wall-papers, carpets, and furniture, but drew blank in every direction. I then suddenly remembered that under the heading of plants I had not specifically mentioned climbers, so I harked back to this. I then learned that there was a "sort of virginia creeper" on the house. It was then winter and the plant was leafless, but I got the patient to send up a branch to Kew for identification, and to my satisfaction the report came back—*Rhus toxicodendron*. This plant, though very well known as a common weed in the United States, is so uncommon in England that people are ignorant of its evil properties. I have only come across two cases of poisoning by it in England, though I believe there is a fair number of plants scattered over the country under the name of *Ampelopsis Hoggii*. At all events, when the cause was once elucidated, the eruption was immediately seen to have a very obvious ætiology, the climber was destroyed, and no further attacks occurred.

Such cases seem simple enough when the ætiology is once elucidated, but much time and trouble is needed in many cases before the offending poison is identified. One point which causes difficulty is the almost incredibly small dose of the idiosyncratic poison which is necessary to produce severe symptoms. It must be remembered, also, that although there is a large number of bodies the qualities of which are well established, there are almost certainly many others which still remain undetected. It is scarcely to be wondered at, therefore, that on occasions the presence of an external intoxication cannot be established, although it may be suspected. As examples of the minute dosage required I may, perhaps, quote two cases.

The first is that of a child, reported by the late Prof. James White[4] in his book on dermatitis venenata. This child, aged 6 years, was twice poisoned one summer with *Rhus toxicodendron*. Consequently the next year a boy who was known to be insusceptible was employed to tear up all the plants growing near the house. This boy was then made to wash his hands, first in hot water with soap and subsequently with vinegar. As a precaution, in spite of his supposed insusceptibility, he was watched during this process by the mother of the susceptible child. In the afternoon this boy took the susceptible child to a pond to bathe. Having stripped him he took him into the water, holding him by the armpits and afterwards rubbing his back with his open palms. Two or three days later the child was taken ill and grew rapidly worse. Deep ulcers appeared under the armpits and the skin of his back exhibited in an aggravated form the usual marks of poisoning by "ivy." He died at the end of the third week of his illness.

The second case to which I will allude is that published by Dr Arthur Hall[5] some years ago.

The patient was demonstrator in a chemical laboratory. In July, 1894, he began to suffer slightly from eczema on his fingers. This disappeared on his vacation, but reappeared on his return in September. He was at this time engaged in a research necessitating the use of phenylhydrazin and benzaldehyde. He gave this up for a time, but at Easter, 1895, he returned to it, and during one of his experiments noticed that a good deal of vapour was given off. The same evening he developed an attack of acute eczema on the face, neck, ears, and scrotum. This slowly died away. On repeating his experiments he developed a fresh attack. In December, 1895, he upset some phenylhydrazin on his hand, and in two hours developed widespread attack. He then gave up experimenting with phenylhydrazin. He was free from December, 1895, to November, 1896, and then had a fresh attack and found that a student was using the chemical in the laboratory.

He was again free until July, 1898, when he got an assistant to do some experiments with it in a room not directly connected with the laboratory. The assistant came and talked with him for a few minutes and another attack resulted. Finally, while convalescing at home from this attack his assistant came to talk with him after walking a mile through the open air, and he immediately developed a relapse.

I now quote a case of the elusive variety.

A lady was sent to me for recurrent attacks of eczema of the hands and face. Her story was that she had fair health, but was very "gouty," and about a year previously had had an attack of "gouty eczema." This had been somewhat resistant, so she was sent to Harrogate where she was cured rapidly. A recurrence took place, and again she was cured at Harrogate. Since then more recurrences had taken place at short intervals. The type of eruption suggested to me an eczema due to external toxin. Close questioning revealed the fact that while on a visit to friends in London the patient was free from trouble, and that on any visit away from home she was also free. This she explained by the rather relaxing climate where her country house was situated. I then inquired for plants, furniture, wall papers, &c.,

and finding that she had a large home farm and dairy, made inquiry as to these. This accidentally put me on the track. The patient had a breed of cows that had very handsome skins, and when any were killed she had the pelts made up into drawing-room rugs. This struck me as so unusual that I turned my attention to these rugs. I then elicited the statement that one of the servants, though not suffering from eczema, remarked that her hands "tickled" after handling the pelts. I therefore suggested that they should be removed and that a part of one should be submitted for analysis to an expert chemist, to whom I made suggestions as to chromium or zinc salts or arsenic. The chemist found nothing suspicious, but the patient had no more attacks for about two years. Her later history is interesting; about two years later I had a letter from her husband saying that after a long period of freedom she had relapsed. He had at once suspected a new source of poisoning, and had found out that she had been knitting a slate-blue wool for soldiers, and that the housekeeper who also knitted this wool complained that it tickled her hands. It was therefore removed and freedom from eczema again resulted. The actual substance was never detected in either case, but the patient was cured and I think I may say with confidence has remained so since.

One further instance I may give of this chemical poisoning.

The wife of a medical man was sent to me for eczema of the face and neck. Suspecting an external cause I made the usual inquiries, but drew blank in every case. I therefore treated it locally and set to work to look for internal causes. In this search the urine and fæces were exhaustively examined, and a bacteriological examination of the fæcal flora was made. Under the local treatment considerable improvement was made, but relapse was frequent and the condition on the whole became worse. After submitting to my failures for some time the patient went to a dermatological friend of mine. He went through the same interrogation and also drew blank. He treated her very successfully with mild doses of X rays in order to subdue the sensibility. Nevertheless although improved she was not free from trouble. Then on one of her visits he noticed a slight change of colour in the hair, and on being taxed she admitted that she dyed her hair, a thing which she had previously denied doing to both of us. It was dyed so lightly that it certainly did not suggest artificial colouring, and when I saw her she had a common shade of brown turning grey here and there. On the day it was detected I suppose she had used a little more than usual, but, of course, I did not see her then. It is not, as a rule, difficult to detect dyeing of the hair when one is examining the patient at close range, but this case illustrates well how by clever artifice and stout denial one may be led away even when one begins with a confident belief in the chemical origin of the eruption.

These are examples of purely local poisoning of the skin, and it will be noticed that in one case the patient had been considered "gouty," and it was believed that the Harrogate treatment had effected a cure, while in another I was myself deceived by the statements of the patient into a tedious search for metabolic errors.

LOCAL PARASITIC DISEASES MAY SIMULATE INTERNAL DISEASE.

I now turn to some other forms of local damage which have given rise to confusion. In 1892 Djelladudin Mouktar,[6] working in Prof. Fournier's clinic in Paris, showed some cases of circinate dermatitis of the sole of the foot. In these cases he found present a ringworm fungus. Being under the influence of the Paris school he attributed these cases to a secondary invasion of an eczema of unknown cause by the ringworm fungus. These cases were reported only briefly in the Transactions of the Paris Dermatological Society and—being published before I was working seriously at dermatology—were unknown to me.

Some time later I began an exhaustive microscopic study of the scales, fluid, pus, &c., which I was able to collect in cases of eczematous dermatitis. The result of these investigations was that in 1908[7] I was able to publish a series of cases of eczematoid eruptions [illegible] the hands and feet in which I had found a ring[illegible] fungus present, but had been unable to cultivate [illegible] on account of overgrowth of contaminating organ[illegible]. However, I described as accurately as I [illegible]uld the type of lesion present, pointing out some [illegible]uliarities that I thought might enable one to suspect the presence of a fungous infection, at the same time contending that it was not justifiable to make the diagnosis of vesicular eczema of the hands or feet without microscopical examination. More than one of my early cases had been diagnosed as, and treated for, "gouty eczema."

In 1910 Sabouraud[8] observed the same set of clinical symptoms on the feet associated with the disease called eczema marginatum, and already known to be due to a fungous infection. Sabouraud succeeded in cultivating the fungus and found it to be the peculiar organism of Dhobi itch, which he had already named the "Epidermophyton inguinale." Unaware of my paper on the subject, he described the disease accurately and also, as I had done, protested against the diagnosis of vesicular eczema and dysidrosis without microscopical examination. Sabouraud in his paper stated that he was acquainted with Djelladudin Mouktar's cases, and that they were not epidermophyton infection. There is also a model in the Saint Louis Museum of one of these, and I do not think it is the same disease as that to which I drew attention.

This disease has several points of interest. In the first place it is, I think, the only case of an infective disease with which I am acquainted which is so much more common in the well-to-do that it may almost be said to be limited to them. This peculiarity has been noted by more than one observer, and is probably the reason for my being able to collect only so few cases in the earlier days of my private practice, since the hospital clinics did not provide me with the necessary material. I have given a good deal of thought to this peculiarity with a view to discovering the reason. It is of course well known that in India the disease is called dhobi or washerman's itch, on the theory that the underclothes are infected by the washerman, though I may point out in passing that the eczematoid ringworm of the feet was not apparently recognised there. This "washerman" theory has met with some antagonism among medical observers; nevertheless I believe it to be the correct explanation in some cases. The well-to-do are at least as clean as the poorer classes, but in most cases they send their underclothes to be washed at a common laundry, whereas the poorer classes generally do their washing at home. That washing will carry the infection is proved by one of my cases, since the maid who washed at home some socks worn by the patient became infected on the hands. No other explanation of the apparent immunity enjoyed by the poor has presented itself to me.

Some of my patients believe that they caught the disease at Turkish baths, and as evidence in favour of this view I may state that I have found the fungus present in the feet of a Turkish bath attendant.

In the second place, there are other phases of the disease which are of interest in connexion with general medicine. The disease may begin extremely acutely with a vesico-bullous eruption and great swelling so that the patient presents the appearance of an acute toxic dermatitis. In this stage it is usually fairly easily curable by appropriate measures, since almost the whole of the stout horny layer is shed en masse and one has only a thin layer to deal with below. If, however, it is not diagnosed but merely treated with soothing applications, the inflammation will slowly subside, and the fresh horny layer will be infected in turn. In other cases the disease may begin quite insidiously with a little scaling, vesiculation, and pustulation between the toes, and this may persist untreated and even unknown for a number of years. It is usually mistaken for a disorder of constitutional origin and labelled "gouty eczema." Slight or severe exacerbations occur in hot damp weather and on severe exercise which induces sweating.

One very important point is that the stripping up of the horny layer and the vesiculation lead to a secondary infection with the pyogenic organisms, especially the streptococcus. This results in persistent fissures between one or more pairs of toes, and from these fissures the infection spreads from time to time up the lymphatics, causing redness and swelling of the leg accompanied by fever. One of my patients developed slowly a chronic elephantoid thickening of the ankle and calf in this way. She was treated for gout on many occasions and visited many watering places, including Homburg, on this supposition, and curiously enough the infection was for some years limited to the right foot. Dr. H. G. Adamson permits me to mention a somewhat similar case under his care, who was for some time in a nursing home in London, and was treated for recurrent gout by a great authority on that disease.

Another case under my care was that of a medical man who developed the disease in its insidious form in one of the Eastern campaigns of the late war, and suffered from a severe relapsing lymphangitis like, and nearly identical with, erysipelas. He was sent on to me, and I found and demonstrated to him the fungus from between his toes, though, as far as my memory goes, he was unaware of anything wrong there. This was some time ago, and I have heard from him since that his feet have entirely cleared up, and that he has been free from all further lymphangitic trouble.

A still more striking case, but of an allied rather than of an identical nature, is that of a male of late middle age who was seriously thinking of undergoing amputation above the knee. This patient damaged his knee in early life and the affection was considered by some surgeons to be tuberculous in nature, by others merely a traumatic arthritis. It cleared up under treatment and he was well for many years. He then began to have recurrent swelling of the leg with sudden attacks of fever up to 105°F. Difference of opinion occurred again and he saw several experts. On analysis of his symptoms I came to the conclusion that the swelling, which was not present when I saw him, was rather in the soft parts round his knee and below it than in the joint itself. I measured his legs and found some slight general thickening of the whole leg below the knee. I then examined his toes, and found a solitary streptococcic fissure beneath the fourth, but could find no fungus present. I therefore treated this and had the satisfaction of hearing from him much later that no further attacks had occurred.

I have dealt with this disease at some length because it appears to me to be so very important, and it is really far from uncommon. As far as I can make out, it became really common in England soon after the Boer War, when it was probably spread by the officers of the Indian Army. It became epidemic in some of the English public schools and was at one time present in one of the large London hospitals, where apparently the baths became the source of infection. The troops in Gallipoli suffered from it almost universally, and the few cases that I have seen in hospital practice have been in soldiers. A disease of this frequency which may be mistaken for gout, neuritis, and tuberculosis by physicians and surgeons respectively must surely be of some general interest!

In concluding this lecture I may confess that I was at one time greatly under the domination of the external factor; and although with increased experience and research I have in some degree altered my position, I am still of opinion that it is only by working patiently through the evidence to be gained by a study of the external and usually more direct factors that one can attain to the degree of knowledge and technique which will enable one to begin to study satisfactorily the internal ætiological factors. For this reason I cannot deprecate too strongly the statement which I have observed in a modern text-book that it is a waste of time to hunt for the acarus in scabies. By constant practice it is quite easy to gain a degree of proficiency which will enable one to extract an acarus in considerably less than one minute. Unless one cultivates the more difficult processes of observation and manipulation one has never the right to give a certificate that such diseases as scabies and ringworm are cured.

THE CAPILLARY PRESSURE AND THE CIRCULATION IN SHOCK.

BY LEONARD HILL, M.B. LOND., F.R.S.,
AND
JAMES McQUEEN, M.D. ABERD.

THERE is no evidence that the capillary wall acts as a soap film and exerts surface tension. Against such a supposition is the fact that the capillaries in the web of the frog's foot do not empty when the foot is amputated. The method, then, adopted by L. Hill[1] of measuring arteriole, capillary, and venule blood pressure is the finding of that amount of compression which, when quickly applied, momentarily arrests the flow. When the compression is gradually raised and kept raised time is allowed for the arterioles to become distended by the pressure of the blood within the artery which is feeding the compressed arteriole, and thus it comes about that the lateral pressure in this artery is measured on blocking and keeping blocked the flow in a capillary field. For example, in the case of the frog's web the pressure in the main artery of the toe is measured, not that in the normally flowing arterioles or capilleries, and in place of a pressure of some 3–5 mm. Hg, which, when quickly applied, momentarily arrests the flow, a pressure of some 25 mm. of Hg is found.

The momentary check occurs when both the kinetic energy and the potential energy of the blood stream are overpassed, for when the flow is momentarily arrested it is equivalent to the sudden damming of the blood flow by the interposition of an impermeable diaphragm across the bore of the vessel; the flow being arrested, its kinetic energy is converted instantaneously into potential energy, and the hypothetical diaphragm is pressed upon by a raised lateral pressure which results from the transformation of the kinetic energy. Similarly, when L. Hill and J. McQueen[2] used a jet of water to play upon the skin behind the finger-nail, and moving it to and fro found the blanching pressure, the blood current being arrested when the pressure of the jet was made high enough, the normal lateral pressure plus the lateral pressure due to conversion of the kinetic energy of the flow was measured. Consequently the accurate measurement of arteriole-capillary pressure measures the total energy, potential and kinetic, of the blood stream.

Now if the force and rate of the heart beat and the calibre of the arterioles, capillaries, and venules be constant, any diminished rate of capillary flow brought about by increased viscosity means a higher lateral pressure. Neglecting that fraction of energy which is dissipated as heat, the diminished rate of flow means less of the total sum of energy expressed as kinetic and more of the total sum of energy expressed as potential or lateral. Similarly, if the capillary flow be quickened through diminished viscosity, the increased rate of flow means a conversion of some of the potential energy fraction. In the first case the lateral pressure rises and the kinetic pressure falls. In the second case the lateral pressure falls while the kinetic rises. When, then, the viscosity of the blood is increased an additional supply of kinetic energy is required to be transmitted from the heart to secure the adequate flow of blood in the capillaries, for as the total lateral pressure and kinetic energy of the arteriole-capillary blood stream is measurable by a very few millimetres of Hg, the kinetic fraction is very small, and it is this very small kinetic energy fraction that is of fundamental importance.

Normally the loss of pressure of the blood in traversing a capillary area is very small. L. Hill found a very small pressure was required to propel the blood along the capillaries in the web of the amputated foot of the frog. The kinetic energy of flow in the capillaries naturally is correlated exactly to frictional resistance of the blood inside the
In normal conditions both the kinetic energy and the frictional resistance due to viscosity

small. Any increase of viscosity has, therefore, a very great slowing effect on the blood current because the kinetic pressure of blood flow is at most a very few millimetres of Hg. In normal conditions of health the body maintains the viscosity just as constant as it does the osmotic pressure or the hydrogen-ion concentration of the blood.

The fact that the total pressure in the capillary field is small is an example of the economy of the body. A uniformly high capillary pressure, such as hitherto accepted—viz., 30 mm. Hg, would mean a corresponding high output of energy from the heart, and this energy would to a large extent be wasted; the most economical way of distributing energy is the method adopted in the body. Energy is supplied where energy is required. By vaso-dilation kinetic energy of blood flow is supplied when the chemical needs of the organ or tissue require it, but be it noted in the body that extra kinetic energy is compensated by less waste of energy where it is not required in areas where compensatory vaso-constriction ensues. Thus changes in the kinetic energy of blood can be secured in certain areas of the body without the heart ever being called upon to supply energy much over its normal amount. For example, when muscular exercise is not undertaken, digestion, absorption, and excretion may make remarkable demands for increased blood flow in large capillary areas with little or no change in the general level of arterial pressure in the main trunks and with quite small changes in the rate and force of the heart. The arterial pressure in the main trunks is utilised where required without any great demand for increased cardiac action. In muscular exercise it is true the heart's rate and force are increased, but such muscular exercise, where systolic and diastolic pressures are much raised, is never maintained over long periods.

Much study has been devoted in man to the recording in health and disease of diastolic and systolic pressures in main arterial trunks. It has been maintained, and no doubt truly, that little material of great clinical value has been obtained from that study. It is true that in those in whom the arteries or kidneys are diseased high systolic and diastolic pressures are often demonstrated. But to expect that clinical information can be obtained from small variations of blood pressure (arterial) is to ignore the meaning of arterial pressure. The arterial pressure exists solely for the maintainance of an adequate capillary rate of flow. Consequently even in cases of abnormally high blood pressure it is safe to say that some essential capillary field demands that height of blood pressure to secure an adequate rate of blood flow. We have no evidence whatever that capillary blood pressure (kinetic factor) is increased in cases of high arterial blood pressure, and if that be proved true by the application of the more accurate method of capillary blood pressure measurement now available, it is safe to conjecture that, if the arteriole conditions remain constant, any great drop of pressure in a person suffering from arterial hypertension will have disastrous results. Stewart records in arterio-sclerosis a diminished rate of flow in the hands.

Similarly, in cases of low arterial blood pressure where the individuals show no symptoms it is certain that the arteriole conditions permit of a quite adequate capillary rate of flow, and to artificially raise the level of general arterial blood pressure, if that were therapeutically possible, would be a work of supererogation. Consequently clinical writers who record arterial systolic and diastolic pressures in disease present only one factor in the problem. It is safe to say that the rate of capillary blood flow in correlation to the arterial systolic and diastolic pressure should be our guide to treatment. The capillary rate of blood flow has a critical value below which it must not fall. That rate in normal individuals is the optimum rate, and it will be found that the body strives even at the expense of a higher arterial blood pressure level to maintain the optimum rate, which may have to be [illegible], for example, in renal disease. If an extra drain is made on the energy of the heart to maintain that capillary rate of flow, there is to that extent a loss of reserve power in the heart. If the arterioles are maintained highly constricted uniformly all over the body an increased force of the heart beat is necessary to maintain the optimum rate of capillary blood flow; and such general vaso-constriction prevents the mobility of the vaso-motor reflexes, and the power of opening the sluice gates in the high pressure arterial system is to that extent impaired. The data of systolic and diastolic pressures in the main arteries so laboriously compiled is then information of little or no clinical value. But it requires to be illuminated and brought into line with the law of an optimum rate of capillary flow.

In the life of the normal individual no falls of any consequence in the level of the arterial blood pressure ever occurs. In fainting, no doubt, a fall occurs, but anæmia of the medulla speedily restores the level of blood pressure, and it is aided, no doubt, by the assumption of the horizontal posture which unconsciousness generally secures. There is evidently a critical level of arterial blood pressure below which it must not go for long periods, and that critical level is determined by the rate of blood flow through the capillaries of the cardiac muscle. Thus, Starling[3] has found that the arterial blood pressure, if it falls below 80 mm. results in a diminished output of energy by the heart muscle itself. If the rate of flow in the capillaries of the heart falls below the level required for the supply of energy of the heart muscle, it is to be expected that grave results will ensue. Such is the case in shock.

The existence of a critical level of systolic pressure in the arterial trunks is the price paid for the maintenance of arterial tone. The fact that the normal capillary pressure (potential and kinetic) is expressible in a few millimetres of Hg while the arterial pressure in the brachial artery may be 130 mm. of Hg, is due to the arterial tone. Pressures are cut down enormously in the small arteries and arterioles, and if they were not so cut down by the tone of the wall keeping narrow the lumen the great alterations in the kinetic energy of the blood streams that are necessary in the periods of activity of tissue or organ would not be obtained without as great alterations in the rate and force of the heart beat. It is this banking up of pressure between the heart and the arteriole which makes of the great arterial trunks a reservoir at high pressure capable of having its sluices opened here and shut there according to the needs of the territory to be irrigated. But the price of the arterial tone has to be paid, and its payment is expressed in the law of the critical blood pressure level. If the arterial blood pressure fall for long periods much below that critical level the rate of capillary flow falls much below the normal. The reason for this is obvious. Attempt at compensation is made by increased vaso-constriction, and while by this means succour is brought by increased pressure in the coronary arteries to the heart muscle and to the brain the capillary field in the body generally outside these areas falls from its already low level of a few millimetres of blood pressure still lower. Vaso-constriction is no cure for an arteriole blood pressure below the critical value. The failure of adrenalin or pituitrin in cases of blood pressure below the critical value is exactly what one should expect.

Fraser and Corvell[4] define a group of cases with primary shock as having a systolic pressure of 40 to 90 mm. Hg; in some of the shock cases they record systolic pressures even as low as 30 mm. Hg. It is to be noted that in these cases the arterial pressure in the main arteries is maintained at these low levels by means of vaso-constriction of the arterioles. This vaso-constriction leads inevitably to a very considerable diminution of the kinetic energy of capillary blood flow. Now the accurate measurement of capillary blood pressure in normal individuals with arterial systolic pressure of 130 mm. Hg shows clearly that the total pressure (lateral and kinetic) in the capillaries is at best a fraction of 10 millimetres of Hg when the normal tone of the arterioles is present. Accordingly it will be obvious that if arterial blood pressures (systolic) fall into a group of 40-90 mm. of Hg and the diastolic pressures are proportionately lower, the total capillary pressure in the capillary areas of the body falls even below its normal exceptionally small level. Consequently the kinetic fraction of the total blood pressure falls still lower, till the blood current in the capillaries must of necessity be extremely slow. Direct observation of the pressure and flow in capillary areas made by L. Hill show that this is so in the state of shock.

In the older estimations of capillary blood pressure as varying from 30-50 mm. of Hg there might have been some possibility of loss of pressure and yet the existence of a remainder of pressure adequate to maintain a capillary flow of rapidity sufficient to supply the tissues with oxygen. In the newer view of the capillary pressure there is little margin available. Hence capillary stasis appears inevitable with its consequences.

Several years ago L. Hill[5] demonstrated the fact that the capillary channels in the body were never all filled. If an armlet be placed on the upper arm and pressure applied just below the systolic level the large veins of the arm below the armlet will rapidly rise to the systolic level of pressure pertaining in the brachial artery while the capillary pressure is still much lower than systolic pressure. Hill deduced from this experiment that (1) the capillaries that have blood in them are capable of taking up much more blood by dilatation; (2) there are numerous capillaries in the body not filled at all; (3) there are anastomotic channels whereby pressure is easily and quickly transmitted between small arteries and the veins.

All of these conclusions have been amply proved. Bayliss found that after section of the spinal cord large volumes of gum saline solutions could be injected and remain in the vessels with persistent dilution of the hæmoglobin, evidently here capillaries distend and formerly closed capillary channels open. The capillary field becomes a huge reservoir of diluted blood. L. Hill finds that direct anastomotic paths between small arteries and veins are visible on examination of capillary fields. Now, it has been repeatedly noted in cases of shock that the red blood cells in venous blood taken from the arm often numbered 2,000,000 corpuscles fewer per c.mm. than in blood taken from the capillaries. In the old view of the circulation of the blood passing by way of arterioles through capillaries into venules and veins it is obvious that the venous counts and capillary counts should agree closely. But if, as L. Hill has long maintained, and now shown by examination of capillary fields under the microscope, there are these short and direct paths between arteries and veins, we should expect that the high red-cell count pertaining in these capillary areas in which there is slow flow or stasis would not obtain in the direct paths through which arterial blood flows with its lower red-cell concentration, hence the venous counts would be uniformly lower than the capillary counts. It is noted that as shock diminishes the capillary and venous red-cell counts approximate in value. In normal individuals greater differences than 3 per cent. between capillary and venous counts did not exist. It is obvious here that in these anastomotic paths we have the factor on which depends the possibility of restoring stagnant blood in the capillary area into circulation. If no such anastomotic paths existed the slowing of the blood current in the capillary area would uniformly lead to concentration so great that little or no blood would be in circulation at all.

Surgical shock would kill with an effect and rapidity similar to anaphylaxis in the guinea-pig; or injection of histamine in the etherised cat, when the blood in the capillaries and veins ceases to flow, as can be observed under the microscope. In surgical shock blood slowly concentrates in the capillary area and the return blood to the heart is a mixture of blood of more normal concentration passing by the direct anastomotic channels and concentrated blood returned from the capillaries to the veins. The phenomena of shock supervene gradually and the removal of shock is equally gradual; viscosity of the blood in the capillaries may be overcome by dilution with other blood (donors), or gum saline mixtures and the pressure in the arterial tree raised through the injection; both factors tend to remove the stagnation. The blood diluted with donor's blood or gum-saline has the easy path of return to the heart via anastomotic channels, and is not compelled, all of it, to force its way through capillaries that are already choked with concentrated blood. The approximation of venous red-cell and capillary red-cell counts is correctly interpreted as proof of the removal of stasis. But if there were not in existence these freer anastomotic paths it is extremely doubtful if such revomal of stasis could take place. The primary cause of the capillary stasis is the fall of the arterial blood pressure below the critical level of 80 mm. of Hg or so, and the fact that the fall is not temporary as in the case of fainting. Whether in shock the products absorbed from damaged tissues or the sensory stimulation preceding it is the cause of this prolonged fall in the arterial blood pressure below the critical level we cannot judge on the available data. However, the fact that with a normal arterial systolic pressure of 130 mm. of Hg the kinetic energy of capillary blood flow is but a fraction of a few millimetres means that this fraction becomes less with a falling blood pressure, and may be still less with a general vaso-constriction in the arteriole area. The general capillary field is sacrificed to the arterial pressure in the brain and in the heart, and a sure Nemesis awaits that method of restoring blood pressure if carried too far. Deoxygenation sets in the capillary area, the osmotic pressure of the tissue cells rises and these imbibe more fluid, the capillary wall may suffer and become increasingly permeable. The viscosity of the concentrated blood increases. The kinetic pressure available in the capillary area, already a small fraction of a few millimetres of Hg is inadequate to maintain the blood flow, and the heart, so carefully shielded from oxygen want by vaso-constriction elsewhere, finds itself with progressively less and less blood to propel.

The value of gum saline solutions or of normal blood from a donor is obviously due to the fact that the heart is fed directly from the vein into which the solution is run. The pressure rising in the main arterial system is transmitted to the capillary area, but the gum saline with its viscosity equal to normal blood, or the donor's normal blood, dilutes the concentrated blood in the capillary area, restores it to a more normal viscosity, reoxygenises the tissue cells and the capillary wall and prevents the increasing loss of fluid by imbibition and permeation.

In shock when the blood pressure falls below 80 mm. Hg it is possible, as pointed out by MacLeod, that the reciprocal innervation by means of which vaso-constriction in one area is compensated by vaso-dilatation in another acts in a faulty manner. It is possible that a profound general vaso-dilatation occurs in the initial stages, but such vaso-dilatation, while it lowers the general level of arterial blood pressure, might not decrease the kinetic energy of the blood flow in the capillaries. But when arterial vaso-constriction sets in later, and blood is trapped in distended capillaries, and capillaries open that formerly were shut, then the kinetic energy of the capillary flow becomes quite insufficient to propel the blood.

The accurate measurement of capillary blood pressure then throws light on stasis. Low arterial blood pressures are dangerous because the capillary kinetic energy of blood flow is very small with normal arterial blood pressure. There is a very small margin of safety in the capillary area.

DIAGNOSIS AND TREATMENT OF DIPHTHERIA.

By FREDERIC H. THOMSON, M.B., C.M. ABERD., D.P.H.,
MEDICAL SUPERINTENDENT, NORTH-EASTERN HOSPITAL, LONDON, N.

IT is quite unnecessary for me to go into the diagnosis of diphtheria in detail, but perhaps there are a few points to which I might draw attention, particularly with the view of early treatment of severe cases. Diphtheria may evince itself in a varying degree of reddening of the tonsil or tonsils and fauces without any deposit, either pultaceous or membranous; as a definite membranous or pultaceous deposit with an amount of inflammation and œdema corresponding more or less to the amount of deposit; as an ulcer or ulcers caused by mixed infection with membrane or pultaceous deposit; or as a most pronounced inflammation and œdema of the fauces with or without a membranous or pultaceous deposit. That may be taken as a very general description of what may be met with in the first day or two of the disease. The very mild attack, productive of inflammation but no deposit, does occur, as we know, by circumstantial and bacteriological evidence, but in a given case we cannot say for certain that the condition is diphtheria.

Usual Form Observed.

Diphtheria usually shows as a membranous or pultaceous deposit (in all pultaceous at first, but usually rapidly becoming an adherent membrane), which looks as if it had been stuck on the mucous membrane, and therefore showing a definitely raised margin. It is ordinarily accompanied by an amount of inflammation and œdema corresponding to the extent of the lesion or lesions, glandular swelling, &c. In some cases the deposit remains pultaceous for as long as a day or two days, and in rare instances never becomes an adherent membrane. Naturally the deposit sometimes occurs in an old ulcer of the tonsil, and may look like an ulcero-membranous condition.

Mixed diphtheria infections are usually due to the added action of septic microbes, the pneumococcus, or the organisms of Vincent's angina, and it is in this class that diagnosis is often difficult, for an apparent ulcerative tonsillitis may be followed by diphtheria; or more frequently the septic condition follows, and doubtless in some the attack may be coincident. I have seen apparent subacute ulcerative tonsillitis go on a couple of days or so, with failure to demonstrate the diphtheria bacillus, followed by the formation of membrane and the presence of the bacillus, and, indeed, one may get any variant. In mixed infections the membrane may not be wholly in the ulcerated area, and I think it is commonly partly out, when the membrane beyond the area will be on the surface and show its raised margin. The deposit may, of course, be pultaceous, just as in pure diphtheria, but the amount of inflammation and œdema is often greater, except in the combination of diphtheria and Vincent's angina.

Features of the Disease in Susceptible Persons.

In those who are peculiarly susceptible to diphtheria the progress of the attack from the time of onset is very marked, and the striking features of this class of case are the rapidly increasing faucial œdema, the rapid swelling of the neck glands, and the increasingly marked accompanying cellulitis. It is this class of case I purpose dealing with more fully later.

Hæmorrhagic diphtheria is a result of toxin circulation produced on a susceptible person, and may be the outcome of a severe attack of pure diphtheria or a severe mixed diphtheria infection, and occurs commonly in the very severe type I have just mentioned, provided, of course, that the disease has not been checked by treatment at a sufficiently early [illegible]. In the diagnosis of an ordinary case of [illegible] diphtheria I only wish to call attention to a statement in a paper on the clinical diagnosis of diphtheria by Dr. H. Drinkwater,[1] published in THE LANCET of May 29th, 1920. He says that in a given case of membranous deposit on the fauces, in the period of growth if it is raised above the level of the mucous membrane, has sharply defined edges, and is single in each affected area as described by him, "there can be no doubt that the disease is either diphtheria or Vincent's angina." If Dr. Drinkwater had not used the words "no doubt" I would be in agreement, but my experience does not permit me to go further than to say that in the great majority of cases the disease would then be either diphtheria or Vincent's angina. But Dr. Drinkwater goes further still and asserts that neither in diphtheria nor in Vincent's angina in the period of growth do we see more than one patch in any one of these six faucial areas. I do not think any experienced observer will agree with him in this, and I have certainly often seen diphtheria commence with multiple lesions on a tonsil, and some of them severe attacks.

Necessity and Difficulty of Prompt Diagnosis.

The peculiarly susceptible individual who develops rapidly increasing faucial swelling, rapid swelling of the neck glands, with accompanying cellulitis, requires prompt diagnosis and treatment. Usually there will be formation of membrane well within 24 hours and the diagnosis will be easy, but a considerable number will show no membrane at the end of 24 hours, and it may even be postponed for 36 hours, though that is uncommon. It is in these cases with late formation of membrane that difficulty in diagnosis arises. In this class there will, of course, be variation in severity, but the fauces will be full of œdema, the tonsils perhaps meeting or nearly meeting in the middle line, and all within 24 hours. The surface of the tonsils usually has a peculiar filmy and translucent appearance, which looks to me like an almost invisible sheeting composed of the thinnest and finest gossamer. The glands at the angle of the jaw will be much enlarged, the cervical glands to a lesser degree, and the neck will be puffed out by cellular infiltration. This class of case will usually die if left untreated for 36 hours, may even die if adequately treated in 24 hours, and very rarely dies if treated within 24 hours. As this severe form of diphtheria is not at all uncommon it is obvious what a saving of life would occur were early diagnosis always possible. It is sometimes diagnosed as mumps, no doubt on account of the cellulitis, but such a diagnosis means that the throat has not been examined. Also such cases are occasionally regarded as quinsy, but quinsy is not nearly of such rapid development, is not common in young children, and a double coincident quinsy is very rare indeed. In severe diphtheria the patient usually opens the mouth well, though there are exceptions, and the difficulty in opening the mouth is usually so great in quinsy that it may be very hard to get a view of the throat. In quinsy at the end of 24 or 36 hours there will be little, if any, cellulitis of the neck.

Differential Diagnosis.

It is very rare to find concurrent quinsy and diphtheria, but I have seen cases of coincident one-sided quinsy and double-sided diphtheria. The differential diagnosis between quinsy and diphtheria will rarely be difficult, but if there is doubt antitoxin should be administered. In the severest forms of septic sore-throat some difficulty may arise in diagnosis, but there will not be thus early much glandular swelling, nor will there be cellulitis, and I do not think I can do better than go back 40 years to quote a very observant clinician. Sir Morell MacKenzie says in his text-book: "In diphtheria the submaxillary and cervical glands frequently become much swollen at the outset of the disease, but in putrid sore-throat these parts in some cases remain altogether unaffected, whilst in others the tumefaction is but slight."

It may be very difficult to differentiate between very severe attacks of scarlet fever and diphtheria at this early stage. Such points as the temperature usually being higher, a sudden onset, commoner initial vomiting, &c., in scarlet fever, are best left alone, as also certain points in favour of diphtheria, such as a probable more rapid cellular infiltration or less faucial pain, &c. To differentiate, one must have a well-defined scarlet fever eruption, and it must be well defined, for an erythema is common in diphtheria; but if that is not present there must be difficulty, and since the patient will be obviously suffering from a dangerous infection, there can only be one course of action and that is to treat for diphtheria at once.

To sum up, I consider that a condition of the throat so acute as I have described must be (except very rarely) either diphtheria or scarlet fever, and must be regarded as diphtheria for purposes of treatment unless definite evidence of scarlet fever is present. That treatment must be as early as possible, and delay of treatment for bacteriological examination is to be severely condemned. As I pointed out in a recent communication[1] on the subject, if the clinical evidence favours diphtheria the patient should be treated for that disease at once.

Treatment of Acute Diphtheria.

I would like to touch upon the main points in the treatment of acute diphtheria; apart from suitable nourishment, these are adequate dosage of antitoxin and complete rest in the recumbent position. All other treatment falls into insignificance beside them, and any treatment which interferes with them is bad. We know that within a certain time antitoxin will stop the production of toxin, but we cannot say just how long that time may be; possibly it varies in different individuals and in different degrees of severity. There is evidence which goes to show that antitoxin neutralises or partly neutralises the toxin in circulation, and that larger doses may partly neutralise toxin loosely combined with the cells, but not that which has become fixed. We do not know at all exactly when the toxin commences to be circulated in quantity; we do not know how long it is in circulation or how long it is loosely combined. The deductions appear to be that the earlier one can treat the disease the better, and that if one fails to get the patient early the dosage should be greater; this is in accord with clinical experience.

At one time it was laid down, and, indeed, is still held by some, that the weight of the individual should regulate the dose. This at first sight seems reasonable, but the child is more susceptible to diphtheria than the adult, and the net result is that the child requires as large a dose as the adult. It is true that infants are often insusceptible or less susceptible to diphtheria, but that point can hardly be held to affect the general rule of dosage. The method of administering the antitoxin affects the dosage to some extent, but the main points affecting it are the severity of the attack and the stage of the disease. It is, however, very difficult to estimate the dosage in any given case, and the only safe method appears to be to err purposely on the ample side.

To arrive at the approximate dose one has to be guided by the stage of the disease, the rapidity of progress from the onset of the symptoms, the amount of membrane, the amount of inflammation and œdema, the amount of glandular swelling, the amount of cellular infiltration; whether the naso-pharynx is involved, as indicated by nasal discharge; the character and amount of the nasal discharge, and whether it is blood-stained; whether there is bleeding from the mucous membranes, and to what extent; whether there is hæmorrhage into the skin, and whether there are subcutaneous hæmorrhages; whether the larynx is affected as well, and the throat fœtor. One must not be guided by the amount of membrane alone, as I fear sometimes happens; I have already pointed out that early in the most serious cases there may often be no membrane. Having thus arrived at the probable dosage it is wise in all severe cases to add, say, 4000 units more to cover possible error.

Intramuscular Administration Preferable.

The accepted methods of administration are the subcutaneous, the intramuscular, and intravenous. The intravenous method, while having its advantages, need hardly be considered for routine purposes. J. D. Rolleston advises the intramuscular chiefly because the absorption is more rapid than by the subcutaneous method. In my opinion, also, the intramuscular method is preferable and the injection is best made deeply into the vastus externus. Some inject into the gluteal region, but as Rolleston points out, the thigh muscles are more compact and exercise greater pressure and so help the more rapid absorption of the injected fluid. Further, it is to be remembered that the patient has to lie on the gluteal region and there is no need to add to his discomfort.

Rolleston advises the following dosage: For severe faucial cases: 16,000 to 20,000 units, and a similar or sometimes smaller dose on one or two of the following days. For moderate faucial cases: 8000 to 12,000 units, occasionally repeated on the following day. For mild faucial cases: 4000 to 8000 units, repetition rarely being necessary. For nasal, laryngeal, conjunctival or aural diphtheria in which there is no faucial involvement: 4000 to 12,000 units.

C. B. Ker states that in diphtheria cases are frequently met with in which a single dose of 10,000 units is not enough, and that in not a few cases there is no improvement until the patient has received more than 20,000 units. Further, he says that in severe naso-pharyngeal cases it may be necessary to give 40,000 units or more. I believe that for some mild faucial cases 4000 units is sufficient, but there is the difficulty of gauging the class of case one is dealing with. This can be done with some accuracy by those of much experience, but is very difficult for others. Personally, I would not care to give less than 6000 units, and I would advise all those who are uncertain that the case is really a mild attack never to give less than 8000 units.

It is well to remember we do not know very much about the accurate dosage of antitoxin; but we do know the patient will recover if an adequate dose of antitoxin is given sufficiently early in the disease. I have already mentioned the wonderfully good results obtained by MacCombie amongst patients treated on the first day of the disease; I believe he never gave less than 12,000 units. It is impossible to say what the maximum necessary dosage is in the most severe cases. I have certainly seen cases in which more than 50,000 units seemed necessary. Ideally the amount of antitoxin necessary should be administered in one dose, but it is very difficult to estimate the quantity and so second doses are often required. It is desirable that the second dose should be given not later than 21 hours after the first; repeated doses extending over a few days are not to be recommended.

—	If treated on 1st day	If untreated		
		Until 2nd day	Until 3rd day	Until 4th day or later
Mild faucial ..	6,000	6,000	8,000	10,000
Moderate ,, ..	10,000	12,000	14,000	16,000
Severe ,, .. Severe faucial & laryngeal ..	20,000	21,000	30,000	30,000
Very severe faucial ..	30,000	40,000	60,000	50,000
Laryngeal only ..	18,000	18,000	18,000	18,000
Nasal only, but with membrane Conjunctival only	6,000	6,000	8,000	10,000

If one has not erred in one's estimate of the severity of the attack, as indicated by a definite increase in symptoms in 12 hours after the injection, many cases will not require more antitoxin. In mild, [illegible] cases second doses will seldom be nec- [illegible] moderate faucial cases some will require [illegible] of from 8000 to 10,000 units. In severe

---

[1] THE LANCET, 1921, i., 1100.

severe faucial and laryngeal second doses of from 12,000 to 16,000 units will be required in a goodly number.

In many very severe faucial cases second doses, usually varying from 16,000 to 20,000 units, will be required, but occasionally it will be advisable to repeat the first-day dose in 24 hours or less if the faucial swelling and cellulitis have increased, and to give a second dose of 20,000 units should there be no improvement by that time. Cases suffering from laryngeal diphtheria with no faucial or nasal involvement seldom require more than the 18,000 units. Nasal diphtheria with membrane but no faucial involvement, and conjunctival diphtheria with no faucial involvement, seldom require a second dose. A discharge from the nose, whether blood-stained or not, in which is found the diphtheria bacillus but no membrane formation, seldom requires antitoxin treatment.

Importance of Recumbent Position.

It is of very great importance that the patient should be in the recumbent position in bed. He should lie flat on his back and unless the disease is mild not even a pillow should be allowed; a mild case may be allowed a soft pillow. The period for which it is necessary to maintain the recumbent position varies greatly with the severity of the attack, but it is wise, except in the mildest forms, to regard the minimum as three weeks, and in very severe cases up to six or even nine weeks. The mildest forms should be recumbent for at least 15 days.

When it is considered safe to move the patient from the flat position the process must be very gradual, the heart being watched with care, and should it be affected by the change return to the recumbent position must be resorted to. In moving the patient from the flat, give only one pillow for a few days, then a second, and so on until the patient may be allowed to lounge in an easy chair at the bedside for half an hour. Even when he is up and about the heart must be watched for some time and the patient put back in the recumbent position if necessary. If this is carried out carefully sudden death in convalescence will occur very rarely indeed.

Some may wonder how one can expect a child to lie flat in bed for weeks, but actually the child suffering from diphtheria will do so readily and almost without exception. With rare exceptions it will be the fault of the nurse, not of the child, if there is difficulty. With the adult, however, difficulty may arise, and considerable persuasion is sometimes necessary. The ordinary case may be carefully moved on his side for changing or blanket bathing, but in a case in which early heart failure is likely the blanket bathing must cease from about the seventh to the fifteenth day, and only those parts sponged which entail no movement of the patient. Every precaution must be taken to avoid unnecessary movement. This complete rest in the recumbent position is laid down as essential by all who are experienced in the disease, and it follows that local treatment of the throat should not be done. It is difficult to depart from a treatment which has been carried out almost from time immemorial, but my experience of local treatment of the throat in infectious diseases is quite unsatisfactory. Even in scarlet fever, whether septic or not, I gave it up some 12 years since, except in the adult, who likes it, and my experience is that in the ordinary case of scarlet fever no difference results, while I think the septic cases on the whole do better, and they certainly do as well. Now in scarlet fever there may be a difference of opinion, but in diphtheria I do not think there should be, for local treatment of the throat must interfere with the complete rest which is essential.

The nursing of diphtheria requires special training, and the requisite nurse is by no means always procurable; indeed, nurses whom one would call capable htheria nurses are scarce. Therefore it is neces- for the practitioner when dealing with this se to tell his nurse not only what to do but also at she must on no account do.

EFFECTS OF
HOT AND COLD APPLICATIONS TO THE SURFACE OF THE BODY

ON THE TEMPERATURE OF THE MUSCLES, LIVER, KIDNEYS AND BRAIN.[1]

By J. J. R. MACLEOD, M.B., Ch.B., D.P.H., F.R.C.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF TORONTO;
AND
N. B. TAYLOR, M.B., M.R.C.S.Eng., F.R.C.S.E.,
FORMERLY CAPTAIN, C.A.M.C., LECTURER IN PHYSIOLOGY, UNIVERSITY OF TORONTO.

(*From the Laboratory of Physiology, University of Toronto.*)

In a previous communication[2] it was shown that the application of heat to the surface of the thigh causes, in the rabbit, an immediate rise in temperature, which spreads laterally for about 20 mm. and penetrates into the muscles for about the same distance, when the application is about 10° C. hotter than the skin. On heat being applied to the surface of the abdomen, at a temperature difference of 15° C. and over a broader area (one-fourth of the abdominal surface), temperature changes were observed to a depth of 75 mm., the lateral spread being 20 mm. That the rise in temperature is mainly dependent upon actual conduction of heat through the tissues, and not due to vaso-dilatation, is evidenced by the fact that the temperature attained in the tissue is considerably above that of the blood, which was recorded in all the experiments by placing a second thermo couple in some deep situation in the body some distance from the place of application of the heat.

In the present communication we desire to report further observations of the same general nature concerning (1) the effect of cold applications on the cutaneous and deep temperatures of the thigh; (2) the effect of heat and cold on the temperature of certain abdominal viscera, viz., the kidney and the liver; (3) the effect of heat and cold on the temperature of the brain. The technique was precisely the same as in the previous experiments, the duration of the period during which the applications of heat or cold were made being about one hour in practically all the observations. The same applicator was used as for muscle. It has a diameter of 33 mm.

I. *Effect of Cold Applied to the Skin of the Thigh (Gluteal Region).*

The effect produced on the subcutaneous temperature by local cold is very marked, and is immediately evident, as shown in Table I., in the experiments of which two thermo couples were used, one immediately under the applicator and the other at some distance from its edge. With a difference in temperature of about 20° C. between the applicator and the skin, a fall of about 13°–14° C. occurred under the applicator, and with a difference of about 23·5° C. the fall was 17 and 18·3° C. In all cases the drop in temperature was very sharp at first, taking about five minutes to reach to within 1·5° C. of the temperature ultimately attained (see Fig. 1). After removal of the cold the temperature of the skin rose at about the same rate as it had fallen.

Regarding the extent of lateral spread of the cooling, it was found that with temperature differences of from 16°–23° C. this was usually evident at any distance up to 25 mm., but not so at 30 mm. This conforms well with the results obtained for lateral spread of heat, in which case, with temperature differences of about 12° C., spreading to about 20 mm. was observed.[3]

---

[1] This investigation is being conducted under the auspices of the Research Committee, Medical Services, Department of Health, Ottawa.

[2] Macleod, J. J. R., Self, A. R., and Taylor, N. B., The Lancet, 1920, ii., 615.

To study the depth at which the cooling penetrates, the needles were placed one of them under the skin and the other in the muscles. In four observations (Table II.), in which the applicator was at a temperature of 21°–23·5° C. below that of the muscle, there was a fall of from 3·9° to 4·7° C. at a depth of 11–15

mm. from the surface. We have not as yet determined the maximal depth to which this effect, or that of heat, might penetrate.

II. *Effects of Heat and Cold on Liver and Kidney.*

Liver.—The thermo couple was inserted in the liver through a small skin incision along the lower border of the costal margin, the applicator being placed over the lower ribs. The exact position of the needle in the liver was determined by post-mortem examination. As might be expected from its great vascularity, the changes in temperature in this organ, for equal differences in temperature between the applicator and the body, are decidedly less than in muscle when heat is applied. This will be evident by comparison of the figures in Table III. of this paper with those of Table III. in the previous paper.[4] In making the comparison it should be noted that the extent of temperature change is given in the present report as the difference between the final temperature reached and the temperature ten minutes *after* removal of the applicator.

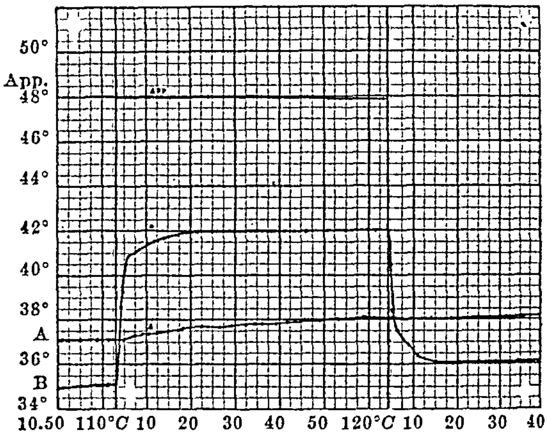
* Difference between initial temperature and temperature reached by applicator.

This procedure was necessary because the body temperature became slightly changed during the hour or so of heat or cold application, whereas this [illegible]ot observed to be the case, as a rule, with [illegible]. A typical curve of the effects of local heat on the liver is given in Fig. 2. The effects of cold are much more marked. Although this fact is mainly due to the much greater difference between the temperatures of the applicator and body, it would appear that there is some critical temperature difference below which the cold has a progressively greater influence. This may be due to vaso-constriction.

Fig. 2.



App.=hot application. Temperatures: A, in liver to depth of 4 mm.; B, in subcutaneous tissue over A.

Kidney.—Under conditions that were, in general, the same as in the case of the liver, similar results were obtained, at least for heat. Although the temperature rose more or less continuously throughout the whole period of application this was due in every case mainly to a rise in body temperature (Table IV.). Considered on this basis—i.e., comparison of final temperature reached with that ten minutes after removal of the applicator—the temperature in the kidney, at whatever depth, never rose more than 0·3° C., even when the applicator was 12° C. higher than the body temperature.

With cold, in which case greater differences in temperature were possible, the effect on the kidney was of the same order as for heat, but in one case it amounted to a fall of 1·7° C., as judged by comparison of the temperature ultimately reached and the recovery temperature. In all these observations the body temperature, recorded in a muscle, either kept constant or fell a small fraction of a degree.

---

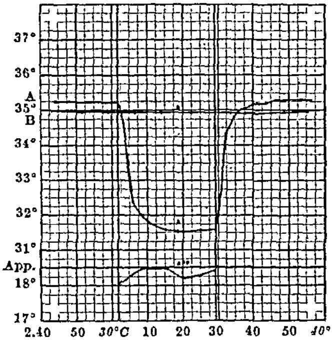
[4] Loc. cit.

The general conclusion drawn from these experiments is that it is not possible to cause any significant change in temperature in the liver or kidney by the local application to the surface of the body over either viscus of applicators that are about 10°–12° C. warmer than the viscus. When the applicator is 20°–25° C. colder than the body the fall of temperature is quite marked in the case of the liver, but usually is insignificant in the case of the kidney.

Effect of Heat and Cold Applied to the Head on the Temperature of the Brain.

In all observations on the brain the temperatures were also taken deep in the muscles of the thigh and in the majority of cases no significant change was observed to be produced on body temperature as a result of the application of heat or cold to the head. In certain cases, however, such occurred, when it was usually in the same direction as the temperature of the applicator. In practically all cases the temperature in brain and muscles bore the same relationship to each other after removal of the applicator as before. It will be observed (Table V.) that application of even moderate degrees of heat—viz., 4·7° and 4·85° C. above body temperature—caused a rise of over one-half degree at a distance of 17 mm. from the surface. With the applicator 7·4° C. warmer than the brain the temperature in the latter rose through 1·5° C. at a depth of 13 mm. and through 0·2° C. at 18 mm. The remaining observations in the table show a satisfactory correspondence between the depth of the thermo couple in the brain and the extent to which the temperature rose. It may be concluded that heat penetrates from the surface into the brain much more than it does in the case of the liver or kidney, although apparently not so much so as into muscle. The changes in temperature are also very prompt both at the beginning and end of the period of application, as is shown in the curve (Fig. 3). In this regard also the results are decidedly ferent from those obtained in the liver and dney.

FIG. 3.



d application over A. Temperatures: A, in brain 14 mm. from skull surface; B, in hip 18 mm. deep.

The result following cold applications are compare with those following heat, thus, with temperature ferences of 7·4° C. and 10·6° C. the brain cooled 5° C. and 1·4° C., respectively, at a depth of mm. Sometimes these effects were still more nounced (e.g., Exp. No. 393). When lower nperatures were used the fall in brain temperature came very marked indeed; thus it fell through ° and 3·45° C. at a depth of about 14 mm., when applicator was at a temperature of about 25° C. ow that of the body. A knowledge of this fact st be of importance therapeutically. The temperae changes were as prompt as when heat was plied.

AN ANOMALOUS RESPONSE TO DIRECT FARADIC STIMULATION OF A NERVE

AT RE-EXPLORATORY OPERATIONS.

BY JOHN S. B. STOPFORD, M.D. MANCH.,
PROFESSOR OF ANATOMY, UNIVERSITY OF MANCHESTER.

DURING the past two or three years re-exploratory operations have been performed upon a number of patients suffering from injury to peripheral nerves, because no satisfactory recovery of function has followed the primary surgical procedure of end-to-end suture or the insertion of a nerve-graft. The results of these examinations of the site of the original operation and the histological investigation of pieces of nerve excised, where re-suture is found to be necessary, are likely to furnish us with very valuable information about regeneration and the factors which may influence the normal development of new conducting channels.

At the re-exploratory procedures a number of surgeons have been surprised to find that on direct faradic stimulation of the nerve trunk a response has been obtained in muscles supplied by the nerve below the lesion, although no voluntary power had ever been detected or any faradic response elicited in the muscles at numerous clinical examinations of the patient immediately preceding the second operation. Several attempts have been made to explain the occurrence of this astonishing and somewhat misleading phenomenon, but so far as I am aware no very satisfactory evidence has been advanced to support the theories suggested for its causation.

An opportunity recently presented itself to me of studying a patient exhibiting this phenomenon, and the conditions found presented a possible explanation, for which further support was subsequently found in a second patient. Since this unusual occurrence of a response in certain muscles on direct faradic stimulation of the nerve trunk may lead to errors in treatment and prognosis, it seems wise to place my findings on record without further delay, in order to see if the experience of others in the future may support or disprove the explanation put forward in this paper.

Private J. H. received a gunshot wound of the left forearm on Sept. 9th, 1916, and this injury was followed immediately by *complete loss of conduction in the ulnar nerve.* Since no recovery occurred after the wound had healed soundly the nerve was explored on April 4th, 1917, by Mr. H. Platt, who found complete division of the nerve trunk and a gap of 1 inch on resecting the ends. As the manœuvre of displacement of the ulnar nerve in front of the internal condyle of the humerus had not then become a routine procedure in cases where an extensive defect was encountered, it was decided to insert a graft from the radial nerve.

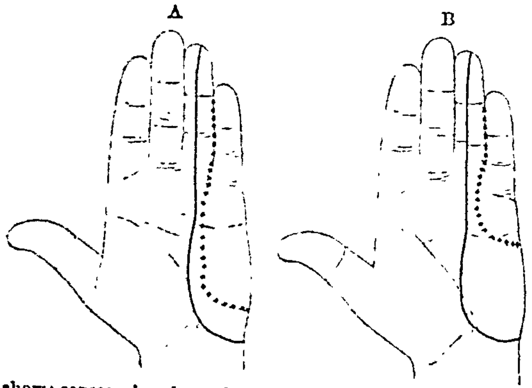
The patient was under observation after operation for a period of nearly two years, when he was boarded out of the army and left the district; up to that time there was no clinical evidence of any conduction through the graft, and the condition of this patient up to that point was included in a recent paper in THE LANCET.[1] He reported at hospital again in December, 1920 (44 months after the insertion of the graft), when there was paralysis, accompanied by wasting and loss of faradic response, of all the intrinsic muscles of the hand supplied by the ulnar.

Being away at the time I did not get an opportunity of making a personal examination until after the performance of the second operation. In view of the above findings he was admitted to the Grangethorpe Hospital and Mr. Platt re-explored the ulnar nerve in the region of the previous operation on Dec. 18th, 1920. Mr. Platt has very kindly furnished me with the following report of the operation: "The ulnar nerve was exposed widely in the forearm through a long incision and the nerve traced up from the wrist to the site of the previous operation. The distal part of the nerve was well-developed but seen to expand slightly as the graft was approached. Faradic stimulation of the distal part caused a definite response in part of the flexor brevis pollicis, in the *adductor pollicis, and abductor minimi* digiti. On exposing the graft the fascial sheath was recognisable and the amount of scar surrounding it was very small and not dense nor causing any compression. The graft was seen as a small well-developed nerve strand extending between the proximal and distal fusiform swellings. These swellings were not at all dense or hard and faded gradually into the graft itself. Faradic stimulation of the proximal bulb, the graft itself, and the distal bulb caused a brisk response in the muscles enumerated above. In view of these findings the nerve was left undisturbed and its covering restored."

---

[1] Stopford, J. S. B.: The Treatment of Large Defects in Peripheral Nerve Injuries, THE LANCET, 1920, ii., 1296.

It is worth recording that the response in the intrinsic muscles was witnessed by five other members of the staff of the hospital and there is no possibility of error. The electrical reactions of the intrinsic muscles were taken several times after the patient had recovered by Dr. J. Cowan, medical officer in charge of the physio-therapeutic department at the Grangethorpe Hospital, and, although a normal faradic response was obtained in the thenar group of muscles, no contraction was ever elicited in the hypothenar group, adductor pollicis, or the interossei.



A. shows sensory loss immediately after insertion of nerve-graft. B. shows sensory loss 44 months later. Continuous line = limit of anæsthesia. Crosses = limit of analgesia to pin-prick.

I examined the patient about one month after the second operation and found an absolute loss of voluntary power, accompanied by advanced atrophy, of the adductor pollicis, hypothenar muscles, and the interossei. There was anæsthesia to the lightest applications of a fine brush over the full area of distribution of the ulnar, but a very appreciable recovery of protopathic sensibility had occurred since my last examination, made nearly two years before. This recovery of protopathic sensibility has been verified by subsequent examinations. There was a positive Tinel's sign as distal as the level of the pisiform bone. No change has occurred during the five months succeeding the re-exploration.

In the history of this patient there are associated two significant features, which seem to bear upon the phenomenon referred to in the opening paragraph of this paper: First, the definite evidence of conduction through the graft; and secondly, the occurrence of some recovery of protopathic sensibility. The history suggests that the graft has happened to be opposed to a bundle of afferent fibres in the proximal segment of the ulnar; on bridging the graft some of these afferent fibrils have grown down in the distal segment and become connected with afferent terminals and are now functioning as manifested by the recession of the protopathic loss; other fibrils may have invaded efferent channels to certain muscles and may consequently be responsible for the response on direct faradic stimulation of the nerve. The central connexions of such fibres as the latter would not permit them to function correctly and conduct impulses giving rise to voluntary movements. It would be unwise even to suggest such a possibility from the condition found in one patient, but on referring to my notes I discovered that the only other patient examined, who exhibited this anomalous faradic response, supported the contention suggested by the first patient.

In the second patient the site of an end-to-end suture was re-explored some two years after the operation, because there had been no recovery ry power or faradic response in any of the muscles supplied by the injured nerve. At the re-exploration a response was obtained on direct faradic stimulation of the nerve trunk, and on reference to the notes I found I had recorded a definite recovery of protopathic sensibility, although the possible significance of the fact had escaped my attention at the time.

The experience gained from a study of these two patients seems to suggest very strongly that the anomalous occurrence of a response in muscles on direct faradic stimulation of a nerve at operation may be explained by the regeneration of afferent fibrils down efferent pathways in the distal segment of the nerve. If future observations prove this theory to be correct it must have an important influence upon the procedure adopted by the surgeon at the second operation. Clearly, if this is the correct interpretation of the ætiology of this curious phenomenon, the surgeon must not be misled and induced by its presence to leave the nerve alone and expect a functional recovery, but must resect the affected piece of nerve and perform an end-to-end suture.

Although at last a patient has appeared showing definite evidence of regeneration through a nerve graft, the condition which this patient presented is not likely to modify the views expressed in a recent communication upon the practical utility of bridging defects by grafts.

TWO CASES OF APLASTIC ANÆMIA.

By E. C. PILLMAN WILLIAMS, M.B., B.S. Lond.,
RESEARCH STUDENT UNDER MEDICAL RESEARCH COUNCIL; LATE MEDICAL OFFICER OF NATIONAL FILLING FACTORY, NO. 7.

AT the present time, when the effect on the blood of long-continued exposure to X ray tubes and radium is being much discussed, it may be of interest to bring forward accounts of two cases of aplastic anæmia, the blood changes in which exhibit a remarkable parallelism with the case of the X ray worker reported in THE LANCET of April 16th last.

CASE A.—Mr. A. K., aged 45, after being passed medically fit, worked for five weeks in T.N.T. sheds. He was then noticed to be slightly jaundiced, and complained of loss of appetite and abdominal pain. He was at once removed from all contact with T.N.T. Five weeks later the jaundice had entirely disappeared. Ten weeks later his general condition was so much improved that he was allowed to resume out-door work. Three months later he began to suffer from shortness of breath and persistent epistaxis. On examination he was found to be very anæmic, and his heart was slightly dilated. He was advised to come into hospital, but refused. Two weeks later he was so obviously worse that he was admitted to hospital under the care of Dr. A. G. Phear. On admission he was found to have a blood count as follows: Reds, 1,528,000; whites, 7200; Hb, 35 per cent.; colour index, 1·5; P., 45 per cent.; L., 53 per cent.; E., 1·5 per cent.; B., 0·5 per cent. He had headaches, epistaxis, retinal hæmorrhages in both eyes, and slight fever in the evening. Despite treatment with arsenic, iron, &c., he got rapidly worse and died on Feb. 16th, just over four weeks from the date of admission.

At the post-mortem the liver (34 oz.) was found much scarred; spleen normal. The bone marrow of the shaft and extremities of the femora was yellow and opaque. Stained smears showed chiefly fat cells, and very few red blood cells and lymphocytes. Stained sections showed that the marrow consisted entirely of fat cells and a few minute islands of lymphocytes. Complete blood counts of this and the next case have been appended for the more easy comparison with the X ray case.

CASE B.—Mrs. P., aged 41, healthy on admission to factory, had worked in T.N.T. sheds for 12 weeks when it was noticed that her conjunctivæ were yellow, and her skin definitely tinged, and bile was present in urine. She was admitted to hospital under the care of Dr. J. W. Carr. After four weeks her condition was so much improved that she was discharged. Five weeks later she was examined and found to have symptoms of profound anæmia. She was very pale, had numerous purpuric spots on the chest, neck, and abdomen. She was again admitted to hospital, and found to have a blood count as follows: Reds, 2,800,000; whites, 4800; Hb, 50 per cent.; colour index, 0·8; P., 21 per cent.; L., 75 per cent.; E., 0·6 per cent.; B., 0·2 per cent. She had headaches, bleeding from gums, BLOOD COUNTS OF THREE CASES OF APLASTIC ANÆMIA.

—	Reds.	Whites.	Hb %	L.	P.	E.	B.	Remarks.
				Case A.				
Jan. 16th, 1917 ..	1,528,000	7200	35	53·5	44·5	1·5	0·5	Reds vary in size; no nucleated reds.
23rd ..	1,248,000	4500	34	54	45·5	0·5	—	
30th ..	920,000	3700	24	61	38	1	—	Some polychromasia.

February, ...	2,850,000	—	45	—	—	—	—	No variation in size.
March 1st	1,350,000	1030	26	72 large 5 small	20	0·5	1 (hyaline)	Poikilocytosis; macrocytes and microcytes; no nucleated reds.
19th ..	1,005,000	840	18	54 large 4 small	41	—	1 (hyaline)	

P., Polymorphs; L., Lymphocytes; E., Eosinophiles; B., Basophiles.

retinal hæmorrhages, and a temperature rising to 100° in the evenings. She went down-hill very rapidly, in spite of treatment by iron, arsenic, marrow tablets, and transfusion of blood, and died on June 17th. Post mortem the heart was in advanced fatty degeneration. Liver also showed fatty degeneration. Spleen normal. Bone marrow yellow and opaque.

It will be noted how close is the general and detailed similarity of the three blood pictures. The symptoms in the three cases are also almost identical. At first sight the "fons et origo" of these cases seem entirely unlike, but it is known that T.N.T. first stimulates and then kills the bone marrow, and long-continued exposure to gamma rays probably has the same action. Most T.N.T. anæmias are preceded by jaundice, but I am not aware that X ray workers are specially liable to this. Among the many thousands exposed to T.N.T. during the war only a very small percentage developed anæmia; probably the same is the case with X ray workers.

I am much indebted to Dr. Carr and Dr. Phear for their kind permission to publish the notes of the cases while under their care, and to Dr. Mary Schofield and Dr. K. J. Armstrong for assistance with the blood counts.

Medical Societies.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

Birth Control.

A MEETING of this Association was held at the Elizabeth Garrett Anderson Hospital on June 21st, with MRS. FLEMING, M.D., in the chair, when a discussion on Birth Control was opened by Dr. ELIZABETH WILKS, who strongly advocated State birth control as the only practical method of prevention of the renewal of the race principally from the worst stocks. She pointed out that to-day the classes superior in intelligence and capacity practise individual birth control (not always from sufficiently justifiable motives), whereas the less intelligent, criminals and prostitutes, have neither the prudence nor the initiative to take any measures for limiting their offspring. Dr. Wilks thought that with a scheme of State birth control the unfit could be segregated and prevented from reproduction, but this should be done in a manner more efficient than that attempted by the Act for the Care of the Mentally Deficient, which fails owing to the insufficient number of homes for maintaining the defectives. On the other hand, by changes in the marriage laws, taxation, &c., an increase of birth-rate among the fit should be simultaneously indirectly promoted.

MRS. SCHARLIEB said that in over 40 years' experience she had found that artificial limitation of birth damaged a woman's nervous system. The thwarting of any natural process caused injury. Limitation of the family is not necessarily, even in the poorest classes, in the interests of the wife. It removes the fear of consequences from the husband, hence encouraging over-frequent sexual intercourse. Mankind is already oversexed. Unbridled sex passions are likely to lead to degeneration and to war against self-control and self-respect.

Lady BARRETT said that the subject was now engaging much attention among the lay public, hence it was very important for medical women to think out their own views. She thought all would agree that in certain cases conception must not be allowed—for instance, in cases of existing disease, insanity, &c., and in working-class women already enfeebled by overwork. In what might be called "ideal cases," where control was practised with a view to enabling parents to look after a few children more effectually it was often assumed, quite unjustifiably, that every woman bears a child every year—it was also forgotten that privation and overwork rather than easy circumstances tended to make for overproduction. How should birth be controlled? In the first place it must be remembered that self-control was a great factor in education and anything leading to the loss of this was harmful. The question of control should be discussed privately and individually. It should not be forgotten that particularly in the working classes child-bearing might have a less harmful effect on a woman than excessive sexual demand. The teaching of what was normal in sex was thus extremely important. Lady Barrett added that she was much opposed to the present broadcast teaching among the lay public. She thought an opportunity for teaching arose at antenatal clinics, where medical women had an opportunity of getting into intimate relationship with mothers.

An animated discussion followed, in which PRESIDENT, Dr. M. STURGE, Prof. L. Mc[illegible] L. FAIRFIELD, and others took part.

Reviews and Notices of Books.

STUDIES IN DEFICIENCY DISEASES.

By ROBERT MCCARRISON, M.D., D.Sc., Hon. LL.D. London: Henry Frowde and Hodder and Stoughton (Oxford Medical Publications). 1921. Pp. xvi. + 270. 30*s*.

Colonel McCarrison's researches into the nature of deficiency diseases are too well known to need any recommendation to medical readers. This book, based on investigations extending over several years, is a most welcome and important contribution to medical literature. Many of the results have been published, it is true, in various journals and proceedings of societies, but their value is increased by being collected and in a measure reconstructed in a single volume easy of access. In his investigations Colonel McCarrison has combined experimental work with close observation of clinical and pathological results of faulty food as manifested in the animal body as a whole, thereby hoping to ascertain what forms of human illness might reasonably be attributed to like causes. He starts with a belief that the term deficiency disease will be found to have wider significance than has hitherto been attached to it. The discovery of the accessory food factors designated "vitamins" gave rise at first to an impression that single constituents in diet played an almost overwhelming part in nutrition as a whole. Against this hasty conclusion Colonel McCarrison enters a well-considered protest. He does not deny that the absence of single food factors may produce striking effects, but he concerns himself more with the complexity of circumstances which may conduce to partial or total deficiency of essential substances. Whilst we are keenly alive to the necessity of recognising the prevalence of the grosser manifestations of deficiency disease, there is a danger of neglecting the lesser signs caused by ill-balanced diets or relatively slight insufficiency of vitamins and other constituents in food. He remarks that frequently it is not the food supplied to the individual, but the food eaten and assimilated which may be dangerously deficient in one or more vitamins, in protein of good biological value, and disproportionately rich in starch or sugar or fats or in all three. Access to abundance of food does not necessarily protect from the effects of food deficiency. "Some there are" he writes "living in luxury, whom ignorance or fancy debars from choosing their food aright." This no less than poverty helps to produce a poor national standard.

Colonel McCarrison's experiments upon avitaminosis were carried out with diets not only deficient in certain factors, but also with diets faulty from excess and want of balance in their ingredients. He imitated as far as possible the ill-balanced diet which in human subjects gives rise to beri-beri—that is to say, a diet devoid of vitamin B and too rich in fats and starch. The result, in pigeons, was loss of appetite, fatty diarrhœa, anæmia, wasting, low temperature, slow respiration, general malaise, and certain nervous symptoms. In monkeys he tried the effects of deficiency in vitamins A and B. The animals developed gastro-enteritis, with unhealthy skin, and nervous symptoms—a state resembling "dry beri-beri" as seen in man. But Colonel McCarrison's observations carry us far beyond mere confirmation of clinical and pathological facts such as these. His attention was arrested by the way in which malnutrition affected various organs in differing degrees. In general, the organs least essential to the life of the individual suffer most, whilst nature does its best to protect the more important structures. An outstanding feature in all forms of food deficiency is enlargement of the adrenals, and in males enlargement of the pituitary. While certain organs enlarge others may atrophy. Colonel McCarrison suggests that the effects of food deficiencies make themselves felt, not entirely perhaps [illegible] [illegible] measure, through derangements of the [illegible] of metabolism.

His conclusions upon these points are so important as to bear quoting at length. The adrenal glands enlarge whilst the thyroid atrophies in the presence of food deficiencies. When the food is excessively rich in proteins and fats, without deficiency of vitamins, the thyroid hypertrophies and the adrenals diminish in size. Atrophy of the pancreas is common, especially in animals whose deficient food is excessively rich in fats, while the pituitary enlarges in males but not in females. The reproductive organs demonstrate both loss of bulk and loss of function. Colonel McCarrison's view is that food deficiency deranges both the normal production of hormones and the functional perfection of the sympathetic nervous control; consequently, the digestive organs are deprived of the full advantage of that efficient regulation and correlation which normally they would derive from healthy endocrine action. As an example of the importance to be attached to these secondary effects we read: "It is known that hypothyroidism may lead to hypoacidity, to impaired secretion of gastro-intestinal juices, to the production in both stomach and duodenum of such lesions as petechial hæmorrhages, superficial hæmorrhagic erosions, acute ulcer, and diffuse inflammation." To adrenal insufficiency he attributes such disturbances as imperfect secretion of gastric juice, gastric ulcer, and derangement of the glycogenetic process, as well as vomiting and dilatation of various parts of the gastro-intestinal tract from failure of the inhibitory effects of epinephrin over unstriped muscle. Similar symptoms may follow pituitary defects.

Enough has been said to show that Colonel McCarrison's work has brought us to the threshold of a new wonder chamber in medicine. As he himself has often insisted, he is only at the commencement of his investigations, and he and the other distinguished workers in this field must not be surprised if their novel ideas meet with tardy acceptance, and even certain opposition. In investigations such as these there is need of men with sufficient imagination to formulate theories, sufficient scientific knowledge to put them to experimental tests; and sufficient judgment to draw conclusions even adverse to their own theories. Colonel McCarrison's book bears evidence that he possesses these qualifications.

The printing and illustration of the work are very good.

CRITICAL MICROSCOPY.

How to Get the Best out of the Microscope. By ALFRED C. COLES, M.D., D.Sc., M.R.C.P. Lond., F.R.S. Edin. London: J. and A. Churchill. 1921. Pp. 98. 7*s*. 6*d*.

Dr. Coles has produced a valuable work on the equipment and manipulation of the microscope for bacteriological purposes, and a serviceable treatment of the subject is compressed within the narrow limits of a handy volume. In the main, the author avoids the discussion of theoretical points, but he breaks away with good judgment from his rule in a passage on a subject, strangely neglected by most writers on the microscope, which he calls the optical index of a lens. Optical index is a measure of the diameter of the beam which the instrument transmits into the observer's eye. In ordinary vision the beam of light by which an object is seen is limited by the observer's iris and may be taken, therefore, to average the eighth or tenth part of an inch in diameter. The microscope is not constructed to transmit, in any circumstances, a beam of greater width than this, and manifestly no purpose would be served even if a broader beam were transmitted, for it would be cut down in passing the pupil of the observer's eye. For low powers, the transmitted beam approximates to this limit. But by an optical necessity the equipment of the instrument for work at higher powers implies the reduction of this diameter, so that with magnification of, say, a thousand diameters it is very common for the transmitted beam to be reduced to about 1/100 inch across, and for still higher powers this narrow beam is narrowed still more, so that, speaking broadly, the diameter is inversely proportional to the magnifying power.

It is many years since Helmholtz pointed out that this law puts a final limit, in theory, to the magnifying power that can usefully be employed, for at a certain point the effects of the diffraction which accompanies this narrowing of the beam is destructive of definition in the image. Thus beyond an assignable limit the more highly magnified image would be no better resolved than one of lower magnification. However, we are far from having yet reached that limit in actual practice, and it seems improbable that we ever shall reach it, for still more serious in blemishing the picture are the entoptic obstructions, teardrops, muscæ volitantes and the like, which such narrow beams render visible in the eye and project as intrusive objects on the image. Only an exceptionally fine eye can tolerate magnification of 3000 diameters and upward in objects visually observed, and only an instrument in fine condition can produce images unspoilt by dust and other obstructions on the back of the objective and lenses of the ocular. Hence for practical purposes this condition is of great importance, although so generally ignored by writers and teachers in their discussion of the microscope. Dr. Coles points out that there are wide differences between lenses of equal magnifying power in this respect, so that one objective may give a beam having three times the optical index of another. This means not only that the lens with the greater optical index yields the brighter image; it means also (and this is certainly of no less importance) that a speck of dust in the instrument or an obstruction in the eye which, completely quenching the beam from one spot in the object, would be seen as a blot in the picture yielded by the lens of low optical index, will be imperceptible in the image yielded by the better lens. The determination of optical index, is not a matter of any difficulty, but if Dr. Coles produces a second edition of this book we hope that he will describe his method of carrying it out, for both in devising and in describing methods of manipulation he has a very pretty faculty.

Dr. Coles's self-imposed rule against theoretical discussion might, we think, have been more often infringed with impunity, even with advantage. For instance, he expresses a definite preference for the old-fashioned paraffin lamp as an illuminant, a view which stands, in our opinion, in considerable need of justification. The paraffin lamp certainly has many drawbacks. It calls for constant attention when in use and requires furbishing up after any long period of disuse. It must be kept at a distance from the microscope or its effluvium will incommode the observer and damage the adjustment of the instrument. At the same time its intrinsic brilliancy is so low that placing it far from the mirror raises serious questions of lighting. Finally, its unsymmetrical form is a distinct handicap in its use for bright field illumination, so that it is useless as an illuminant for high power work except under the condition known as critical illumination. These are drawbacks from which electric light relieves the microscopist. In the case, especially, of the new gas-filled lamps of the "half-watt" type the intrinsic brilliance of the illuminant is so great that with it the observer of to-day can accomplish things that the worker with the paraffin lamp cannot even dream of. It is true that the naked filament is an unsuitable source of light, but the simple expedient of covering it with ground glass secures a light source which, being broad and symmetrical, gives a perfect image whether focused in the same plane as the object or not, and its adaptability puts the microscopist in a position to take great liberties in other respects with his illumination.

Whatever view readers may take of the choice of illuminant they will certainly find recommendations in this book of great practical importance. For example, Dr. Coles makes use of small-sized photographs when taking notes of his work. Photomicrography in a simplified and cheapened form might be made an important aid to note-taking by bacteriologists and others. Dr. Coles illustrates the use of such notes, of which as many as sixteen can be taken on a single quarter plate. He also describes a simplified camera for use in this connexion. This camera has many good points, but they are outweighed by the fact that the microscope has to be taken to the camera every time a photograph is to be taken. We remember to have seen a handy photomicrographic camera on the market before the war, which not only produced negatives of small size (in this respect Dr. Coles's 1/16 quarter plate has a marked advantage), but possessed also the merit that it could be brought to the microscope and used in place of the observer's eye without any change of adjustment, provided the instrument was in the upright position. This is how a note-taking camera can most conveniently be used.

Dr. Coles gives useful chapters on colour screens, centreing, tube length, dark-ground illumination, staining and mounting, and other matters of practical interest. His book is a practical vade mecum, written by a skilled and experienced operator, whose opinion on all points is worthy of consideration and whose experience is placed freely at the service of his readers.

MANUAL OF MIDWIFERY.

Third edition. By HENRY JELLETT, M.D., F.R.C.P.I., late King's Professor of Midwifery, Trinity College, Dublin; ex-Master, Rotunda Hospital; and DAVID G. MADILL, M.B., B.Ch., B.A.O. Dub., Gynæcologist, Monkstown Hospital, Dublin, ex-Assistant Master, Rotunda Hospital, Dublin. London: Baillière, Tindall and Cox. 1921. With 20 plates and 540 other illustrations in the text. Pp. 1266. 42s.

As some eleven years have elapsed since the appearance of the second edition of this work a good deal of revision has been necessary. In this Dr. Jellett has had the advantage of the assistance of Dr. Madill. The book has been thoroughly revised and in large part rewritten. It still, however, maintains its characteristic features and is a most interesting record of the practice of the Dublin School of Obstetricians. The whole comprises some 1200 pages, and when we note that it is practicallythe same size as two of the most popular text-books on medicine and surgery respectively, we must conclude that it contains a very full exposition of the subject it deals with. At the same time it is a pity that authors cannot keep their text-books within a more manageable compass. It appears to us obvious that if the whole subject of medicine can be well and thoroughly discussed in a book of the same size as this, the much smaller and certainly less important subject of obstetrics might be quite adequately dealt with in a less bulky tome. We are not wishing to detract from the value of the book; we are only concerned with the unfortunate student who has to wade through these monumental text-books in the short time he has at his disposal for reading.

We notice a good many differences from the teaching given in the second edition; one would expect this to be so after an interval of so many years. In so well known a book, which has reached a third edition, it is unnecessary to do more than allude to a few of these. The description of the development of the membranes in the human ovum is still somewhat confused, as the author does not sufficiently distinguish between the facts as *known* in the lower animals and the condition which is *assumed* to occur in the human ovum. The description of the mechanism of labour in the vertex presentation has been revised and brought more up to date. The account of the management of the third stage and of the use of the Dublin method of expression is interesting, and affords a very clear guide to the proper method of conducting this stage of labour. We note, however, one curious statement—that the fundus of t uterus before the separation of the placenta lies only slightly above the pubes!

Twilight sleep is not highly approved. The various methods of dealing with a face presentation are described well and in considerable detail. In dealing with shoulder presentations the author adopts the useful classification of Winckel. It is interesting to notice the recommendation of laparotomy in the treatment of an irreducible incarcerated retroverted gravid uterus. In considering the treatment of eclampsia, the use of morphia is recommended, combined with the administration of nothing but water by the mouth; only if, in spite of medical treatment, the condition of the patient is becoming worse should the uterus be emptied, after dilatation of the cervix with a hydrostatic bag or a mechanical dilator. Accouchement forcé and Cæsarean section are not recommended. In considering the treatment of placenta prævia, version as a general rule is advised. The figures of Döderlein are quoted as showing that the contention that an improved prognosis for both mother and child is obtained by the performance of Cæsarean section is not justified. The section on contracted pelves is particularly good. The figures are excellent and there is a full index.

This edition worthily maintains the high reputation achieved by former ones; the book is a very good one. The good results obtained at the Rotunda Hospital over a long series of years render these conclusions of the highest importance.

PSYCHO-ANALYSIS.

Psychanalysis in the Classroom. By GEORGE H. GREEN, B.Sc. Lond., B.Litt. Oxon. London: University of London Press, Ltd., and Hodder and Stoughton, Ltd. 1921. Pp. 176. 7*s.* 6*d.*

THE psycho-analytical method, first developed empirically as a means of medical treatment, has been extended to the general study of human thought and behaviour, and since analysts claim to find a mass of infantile material in the adult unconscious it was to be expected that the method would be specially applied to the study of educational problems and the life of the child. "Psychanalysis in the Classroom" (which, in spite of the spelling, is by an English educationist), is an attempt to give teachers and parents sufficient of the new teachings to enable them to understand the difficulties of the child and to assist him in making adaptations that will help towards happiness and success, not only in school life but in adult years. Mr. Green has given us a book in which sex is mentioned only in the final chapter. He describes the antagonisms and fixations of family life whilst making little use of the technical terms of analytical psychology or names derived from Greek story. Yet the reader familiar with psycho-analytical literature will recognise old friends in homely garb and will admit that within the limits the author sets himself he has done justice to the subject. Only one serious criticism must be made; he uses "repression" in a popular sense to indicate conscious control of one's desires or even control imposed from outside; as when he writes (p. 91), "Repression affords . . . gratification to the person who imposes it." This is confusing, for the psycho-analyst uses the word to indicate a process by which desires are thrust into the unconscious, the person concerned being unaware of their presence; control of these desires is lost and impulses from them may rise into consciousness to produce irrational actions or psycho-neurotic symptoms. Hence repression in the psycho-analytical sense is often associated with loss of control, and control is restored by bringing the repressed material into consciousness. Mr. Green himself gives illustrations of this process of restoring control by abolishing repression, which is the aim of psycho-analysis.

With this exception the book gives a fair exposition [illegible] theory of the unconscious, which is presented [illegible] palatable and easily digested form. "A man [illegible] go through the world successfully as a mother's boy, though many thousands are trying," is a fundamental proposition of psycho-analysis which Mr. Green illustrates by his own material; that the fear dream may be a wish fulfilment is intelligible in the light of his examples, and he has paid special attention to the phantasy-life of the child. The chief aim of education, according to Mr. Green, is "to discover the nature of the deep instinctive motives of children, and to train them from egoistic levels of expression to altruistic levels." He endeavours to show that this is not a platitude but that the training depends upon sublimation—a transfer of interest without change of motive; that sublimation is more effective when there is no consciousness of what is really being done, but that the teacher or parent can understand the instinctive motive of the child only by some familiarity with psycho-analytical principles.

Of medical interest is the case of a girl who suffered from eye trouble at the approach of each school examination; on each occasion the ophthalmologist gave instructions that she was to do no work till new glasses had been made; so she is "able to sit and build airy castles whilst her fellows actively compete against each other." It is disconcerting to feel that the author regards the ophthalmologist as concerned only with the eyes and not with the patient. The last chapter is a brief survey of the growth of the sex instinct and of its relation to life as a whole, and contains a warning that our traditional methods of handling the sex curiosity of the child lead to results which are the opposite of what we desire and expect. There is surely a negative omitted on p. 252, where we read "the instinct of hunger has necessarily been repressed," and on p. 207 "auristic" should be "autistic."

The work is one of the simplest accounts of psycho-analysis that have yet appeared, and the author has surmounted the objections that are often raised to presentations of the subject to lay readers.

The Problem of the Nervous Child. By ELIDA EVANS. With an introduction by C. G. JUNG, M.D., LL.D. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1921. Pp. 299. 12*s.* 6*d.*

THIS volume, written by an American lady engaged in the psychological treatment of both children and adults, treats the problem from the standpoint of the Zurich School; an introduction by Dr. C. G. Jung describes essential principles clearly and briefly and is a help to the proper understanding of the book. Mrs. Evans, following Jung, regards the nervous child as suffering from a checking of the libido; treatment consists in directing its energies, partly by making the child's own motives conscious, but chiefly by altering the environment, so that the conflict between *what is* and *what is* (unconsciously) *desired* may be satisfactorily settled. This seems easy, but behind it lies the implication that the parent is often responsible for the neurosis, and throughout the book is the repeated plea for the protection of the child from the parent. That the tight grasp of overpowering authority must lead to effort to break away or must produce weaklings and failures is perhaps strong meat to the old-fashioned parent, though he would perhaps not fit the cap to the head; and it is stimulating to any parent to be told that "the manifestation of puberty which evokes the most perverse behaviour on the part of the parent is the child's first love affair." Extreme tenderness, according to this school, produces an equally bad effect, and the sweet and indulgent mother becomes the son's ideal of the dearest and loveliest woman; this is a rather too simple explanation of the *Œdipus complex*, but serves as an example of an infantile fixation of the libido that may lead to dependence upon childish ideals in adult life. The question of *when* a child should be told about sex matters is answered plainly (there seems general agreement nowadays that the child *should* be told); sex education must be faced as soon as questions are asked, otherwise all sorts of weird phantasies about sex may be passing through the child's mind.

The chief aspects of modern theory are dealt with; technical terms are avoided, and there is nothing that should offend the open-minded reader. Yet there are many defects: over-enthusiasm may be forgiven, but lack of coherence and accuracy is not atoned for by a picturesque style. We read the first chapter—Statement of the Problem—and find no problem stated; in fact, we are not sure what is meant by the "nervous child" except that he is an immature form of the nervous adult. On p. 166 the sentence ". . . loss of sex power, whether from castration, impotence, or sterility in the male, ovariotomy and barrenness in the female, leads to neurosis and degeneration . . ." leaves us wondering what is the difference between impotence and loss of sex power; moreover, analysts, as a rule, regard impotence as a result, or a constituent part, of a neurosis rather than a cause. The medical man, psycho-analyst or not, can only look amazed at the statement that "in the unconscious there is a secret which the aphasia victim is afraid of betraying, and he guards it by using inappropriate words," and hope that the writer does not mean what she says. Enthusiasm speaks on p. 55: ". . . the experienced psycho-analyst can clearly see during the narration of the patient's first dream the exact cause of the trouble"; then follows a warning against "telling the patient at the first interview the whole story of his neurosis." The first statement is likely to be repudiated by the experienced psycho-analyst himself, and the corollary is a warning against the impossible. Even these criticisms have their dangers, according to Mrs. Evans. On the title page of her book is the maxim "He who reads to criticise seeks only to hide his own defects, but he who reads for understanding will find the truth." To this the critic could answer that the maxim, even if true, must fail in its intent, for, as the author says elsewhere, "telling a person of a moral defect never cures him."

The Sex Factor in Human Life. By T. W. GALLOWAY, Ph.D. The American Social Hygiene Association. Pp. 142.

THIS book, written for American college students, is a plain-spoken discussion of the desire for sexual intercourse on the part of the male and of the need for its control and direction in the interests of the individual and of society. The book enables us to examine a non-analytical view of conduct, for Mr. Galloway regards the "sex factor" as being entirely on the conscious plane, and shows the influence of new ideas only by one casual reference to repressing desires into the "unconsciousness" (p. 36) and by the use of the word "sublimation" in a chapter title. Sublimation "implies that the individual has imagination enough to look ahead and to believe that it will pay in satisfaction to give up the present physical enjoyment for the later and larger social, more humane, and complete enjoyment" (p. 33). If the desire for enjoyment were the only motive for action—sexual or other—and the individual were fully aware of the motive and the results of the action, then the road to happiness would be clear. But love is blind, and even in other spheres than love neither exhortation nor reasoning suffices to control the urge of the unconscious motive. The author shows no knowledge of the view that the most effective sublimation is carried out unwittingly, and he would repudiate the explanation that his own interest in bringing happiness to youth may be a successful and desirable sublimation of one component of the sex instinct. The limitations of his views are best shown by the phrase (p. 114), "Inconsiderate coldness in sex relations on the part of the wife." This condemnation of "coldness," as if it were within the control of the sufferer and to be removed by a homily, is reminiscent of the father who threatened to chastise his family unless they were cheerful. "Coldness" (which is, perhaps, as common on the part of the husband as is "inconsiderate lust," though the author's narrow treatment of the "sex factor" does not allow this to appear) is, as he points out, destructive of home life, and his easy dismissal of its difficulties is sadly insufficient. Yet he could not do otherwise; he applies the principles of logical reasoning to the government of mental processes, and when these processes are inaccessible to reason he must surely fail. Shakespeare wrote:—

> "Affection,
> Mistress of passion, sways it to the mood
> Of what it likes or loathes"—
> *Merchant of Venice.*

and the passage from which this quotation comes presents so well the idea of the unconscious motive that we need not call upon psycho-analysis to refute the intellectualist fallacy as applied by Mr. Galloway to sex emotion.

Restraint, training, and guidance are necessary in regard to human action, whatever theories we hold; Mr. Galloway's efforts in this direction are all to the good, especially as he stresses the need that substitute outlets for sex energy should be useful socially, with satisfaction to the individual. The book is full of sound advice, and as a "straight talk to young men" on sexual indulgence should fulfil a purpose; but measured by its title it is disappointing.

TEETH AND HEALTH.

By THOMAS J. RYAN and EDWIN F. BOWERS. London and New York: G. P. Putnam's Sons. 1921. Pp. 264. 7*s.* 6*d.*

THE object of this book is to place before the lay reader the part played by the teeth in the maintenance of a normal standard of health. The authors, have, we think, been a little too ambitious and have produced a book which contains much detailed pathology and which in that way may weary the layman and defeat the object of the work. For example, there is a chapter extending to 30 pages on Focal Infection and another of 10 pages on "Why we need an X ray examination." In the latter chapter we are informed that if President Roosevelt had undergone a thorough X ray examination of his teeth by a competent dentist he might still be alive.

HISTORY OF SCIENCE.

Eminent Chemists of our Time. By BENJAMIN HARROW, Ph.D. London: T. Fisher Unwin, Ltd. 1921. Pp. 248. 9*s.*

Dr. Harrow is probably best known to British readers as the author of an illuminating little book called "From Newton to Einstein," which gives a most simple and intelligible account for non-mathematical readers of the theory of relativity. In this, his latest book, Dr. Harrow writes a series of short lives of eminent modern chemists, men whose researches have been of vast importance in pure science and also in commercial fields. Chemistry and chemical researches have a most curious way of becoming influential in regions which at first would appear to be quite outside the sphere of chemistry. No one, for instance, would have thought that the synthetic preparation of quinine would have any possible influence upon public health, bacteriology, agriculture, and explosives. Yet Perkin's researches into the synthesis of quinine led to the coal tar dyes whose use in bacteriology is known to all, while the discovery of alizarin and artificial indigo respectively nearly ruined the madder and indigo planters. Again, Madame Curie's work on radium upset all our preconceived theories of atoms, and when Ramsay found helium on this earth few would have thought of the possibility of its being used to produce the non-explosive airship. Romances such as these will be found in plenty in Dr. Harrow's pages.

Mediæval writers held that theology is the Queen of sciences, because theology is the knowledge of God, and such knowledge implies a knowledge of all His works. Much, however, still remains [illegible] known, and theology is getting assistance [illegible] sides. It is encouraging to look back an [illegible] much light has been thrown of late years [illegible] of the problems confronting us. When of the work of Ramsay on the gases of the atmosphere, of Mendeléef on the periodic law (a law which had been to some extent foreseen by Newlands in 1866), of van't Hoff in stereo-chemistry, of Arrhenius on electrolytic dissociation, of Fischer on enzymes, of Richards on atomic weights and their relations, we see how the light is shining in dark places. Dr. Harrow says that he has ready for publication a second volume which deals wholly with the work of chemists, and we look forward with pleasure to its appearance.

Studies in the History and Method of Science. Edited by CHARLES SINGER. Vol. II. Oxford: At the Clarendon Press. 1921. Pp. 559. 48*s.*

THE first volume of this series appeared in the autumn of 1917 and was reviewed in our issue of Jan. 26th, 1918. The editor, Dr. Singer, who was unable, owing to his absence on military duty, to see the volume through the press, has been able to preside at the birth of Vol. II., and contributes an illuminating introduction dealing with the work now being done in the study of the history and philosophy of science, not only in this country but throughout Europe and the United States. Besides this introduction he has provided a discussion, which forms the opening paper of Vol. II. on Greek Biology and its Relation to the Rise of Modern Biology. Greek science, he points out, sprang from Greek philosophy and never lost direct touch with that philosophic stem; modern science, on the other hand, owes but little to philosophy, but grew from slow and painful observation and experiment.

Modern observers do not, as a rule, think; they try. Aristotle, though in many ways only a careful observer, laid down a rule which led men wrong until the time of Galileo—i.e., concerning falling bodies. He said, "We see that bodies which have a greater tendency of heaviness or lightness, if they are otherwise similar in shape, pass more quickly through the same space, and in the ratio which the magnitudes have to each other." Now Galileo *tried* his experiment with the ten pound weight and the one pound weight let fall from the top of the tower of Pisa and found that they reached the ground at the same moment. It is true that modern scientific workers sometimes have made a great discovery by thinking, as in the case of the discovery of Neptune by Leverrier and Adams working independently, but most of our recent advances follow on experiment. Aristotle was, however, a great and accurate observer in the field of biology, and Dr. Singer gives many instances of his work, notably that upon the development of the chick. Aristotle gave a good description of the generative process in cephalopods, known as hectocotylisation, though in another passage he contradicted this account, but the matter was not cleared up until Kölliker's observations. The process of sexual congress in the octopus was watched in a tank specimen and figured by Racovitza, whose illustration is reproduced on p. 46 of this volume, where the appearance of the male octopus irresistibly reminds the reader of Moore's "Veiled Prophet." Dr. Singer further discusses the botanical observations of Theophrastus compared with those of early modern botanists such as Highmore and Malpighi. His article is most interesting and beautifully illustrated.

All the 15 papers contained in this volume call for comment. Perhaps the most interesting of those to which we can only call attention, at least to a medical man, are that by Dr. E. T. Withington on the Asclepiadæ and the Priests of Æsculapius, and that by Mr. H. Hopstock on Leonardo as an Anatomist.

Dr. Withington discusses the vexed question as to whether the Asclepiadæ—i.e., the physicians, were so called because Hippocratic medicine had its rise in the temples of Æsculapius. Various scholars of great authority have answered this question in the affirmative, and various others of equal authority in the . Dr. Withington is with the latter and gives asons for his belief. The anatomical and ical papers of Leonardo da Vinci are preserved at Windsor and have been published and edited in the French, Italian, English, and German languages in Paris, Turin, and Christiania. Mr. Hopstock is one of the Norwegian editors of the "Quaderni d'Anatomia," published in six volumes at Christiania 1911-1916, and his article gives a vivid picture of Leonardo's genius in one of the many fields of knowledge wherein that astonishing man worked. Other papers are those of Mr. Robert Steele on Bacon and the State of Science in the Thirteenth Century, and Mr. Fahie's account of the Scientific Work of Galileo.

Dr. Singer is to be congratulated upon a most interesting volume, one which is in every way worthy of its dedication to the Memory of William Osler.

STRING FIGURES.

Second edition. By W. W. ROUSE BALL, Fellow of Trinity College, Cambridge. W. Heffer and Sons, Ltd. 1921. Pp. 69. 2*s.* 6*d.*

THERE is a period of convalescence when the eyes are weary of reading, when visitors seem infrequent or are excluded altogether, and when games that have to be played on boards, and even jig-saw puzzles, require a forbidden change of posture. It is then that detailed instructions which can be read aloud, enabling the patient to make representations, more or less recognisable, of familiar objects with no further apparatus than a piece of string six or seven feet long and his ten fingers will be welcome. The fact that most of the designs described in Mr. Rouse Ball's engaging little book have been learnt from Eskimos, Red Indians, from natives of Central Africa, the Pacific Islands, and the Torres Straits, and many other places, brings adventure to the bedside. The illustrations show clearly what is to be aimed at and the skill required for the simple patterns is not great. Especially useful would be this pleasant occupation to those whose fingers require re-education for whatever cause, and medical men might recommend the little book to many anxious mothers.

RESEARCH LABORATORY PAPERS.

Collected Papers from the Research Laboratory—Parke, Davis and Co., Detroit, Mich. By Dr. E. M. HOUGHTON, Director. Reprints, Vol. VII. Detroit. 1920. Pp. viii. + 490.

A SERIES of 49 reprints (Nos. 145—193) of original articles dealing with a wide range of medical, pharmaceutical, veterinary, pharmacognostical, and botanical subjects makes a volume of nearly 500 pages, well printed on good paper and illustrated by photographs and drawings where necessary. The Treatment of Burns by the Application of Paraffin, by G. I. Walters, shows that while paraffin gives consistently good results, yet the final effect varies with certain factors, which are discussed. Mr. Walters, to demonstrate the value of paraffin, quotes critical experiments and makes suggestions for the further improvement of this method of treatment by incorporating antiseptics and serum derivatives. Studies in Diphtheria Toxin, by L. Davis, deals with the conditions of hydrogen-ion concentration in a bouillon broth, which are most favourable for the production of a diphtheria toxin. The Cultivation of Medicinal Plants, by O. A. Farwell, discusses the kind of knowledge required for cultivation on a successful basis of various plants. Belladonna, henbane, digitalis, and hydrastis are considered in detail. A paper by M. C. Hall gives an account of exhaustive experiments made to determine the best methods for the Control of Lice on Horses, with especial reference to Winter Conditions. The use of coal-tar dips, of volatile substances such as methyl alcohol, of fatty and oily substances, including horse-fat, of powders such as naphthalene, and of fumigation with gases such as sulphur dioxide are considered in turn. Other sections are equally useful, and the whole volume, in fact, provides much interesting and suggestive reading.

JOURNALS.

British Journal of Experimental Pathology, Vol. II., No. 3, June, 1921.—Evans, C. L.: The Reaction of the Blood in Secondary Anæmia. Although the immediate effect of hæmorrhage is a lowering of the alkali reserve of the blood, the response of the respiratory centres may partially compensate, or even over-compensate, for this change, so that the circulating blood may be either more acid, or less acid, or of the same reaction after as before the hæmorrhage. After 12 hours the reduction in alkali reserve is compensated, owing to increased excretion of acid by the kidney; subsequently the alkali reserve of the blood may become higher than the normal and remain at this level until the corpuscular regeneration is complete. The response is a protective one against acidosis.—MacNalty, A. S.: The Morbid Histology, Bacteriology, and Experimental Pathology of Encephalitis Lethargica. A critical review.—Yorke, W., and Macfie, J. W. S.: The Mechanism of Autolysis in Paroxysmal Hæmoglobinuria. When the blood of a case of paroxysmal hæmoglobinuria was cooled at 0° C. for five minutes only, before warming at 37° C for one hour, the amount of hæmolysis which resulted was about ten times as great as that which occurred when the cooling was prolonged for 30 minutes. The explanation of this depends on the facts that in hæmoglobinuric serum immune body is greatly in excess of complement, and that sensitised red cells take up the mid-piece of the complement at 0° C., whereas the persensitised erythrocytes can only absorb end-piece at higher temperatures. Many more erythrocytes are sensitised after cooling for 30 minutes than for five minutes; consequently, mid-piece is diffused amongst a correspondingly greater number of sensitised erythrocytes. On warming, the concentration of end-piece available for each persensitised erythrocyte depends directly on the number of these, and when the number is very great (e.g., after cooling 30 minutes) the concentration is insufficient to produce lysis. The immune body erythrocyte reaction is reversible, but ceases to be so as soon as the erythrocytes have become persensitised. Experiments conducted with the object of determining whether the immune body is thermostable or thermolabile were inconclusive.—Fildes, P., and McIntosh, J.: An Improved Form of McIntosh and Fildes's Anaerobic Jar. The palladium-asbestos capsule of this apparatus is electrically heated to maintain its activity indefinitely.—Jensen, Vilh: A New Immersion Fluid. This is a mixture of liquid paraffin and α-bromnaphthalene adjusted to a refractive index of 1·515.—Douglas, S. R., and Fleming, A.: On the Antigenic Properties of Acetone-extracted Bacteria. (1) Acetone-extracted bacilli form a convenient way of storing bacilli and apparently keep their antigenic properties unchanged indefinitely. (2) They are very easily dissolved by tryptic and other proteolytic ferments. (3) When employed as vaccines, acetone-extracted bacilli appear to have antigenic properties fully as great as vaccines made by other methods. (4) They also form a very suitable antigen for use in complement-fixation tests. (5) Suspensions of these extracted bacilli are agglutinated by immune sera only after a long period and by dilutions more concentrated than is the case with suspensions of living or formolised bacilli. (6) Preliminary experiments appear to show that acetone-extracted bacilli which have been digested with trypsin when injected into animals produce a marked increase (equal to or greater than undigested bacilli) of the bactericidal power, but the increase of the agglutinating power is very much less marked.

American Journal of Ophthalmology, May, 1921.—A paper by M. Uribe-Troncoso, of New York, on the Physiologic Nature of the Schlemm Canal, reviews the various investigations regarding the function of this canal and reopens the old and protracted controversy as to whether it is a venous sinus or a lymph space. In 1873 Leber first advanced the view that Schlemm's canal is a venous sinus and this is the view almost universally held to-day. In this country it has received the support, among others, of Thomson Henderson. Uribe-Troncoso, however, relying largely on the work of Maggiore, of Rome, brings forward evidence to prove that the canal has the structure of a lymphatic, not of a vein, and concludes that the results of observing the irido-corneal angle in living eyes by the contact glass method of Fick and Salzmann, when the canal is found to contain clear fluid and not blood, further supports the lymphatic theory. A description is given of a method of collecting or measuring the fluids from the plexus around the limbus in the rabbit's eye. The low blood content indicates that the fluids thus obtained are largely of lymphatic origin. The paper is a very interesting one, and more work on this problem may be looked for now that methods of adequately examining the living eye with high magnifications are available.—Harold Gifford discusses shortly various methods of fixing the eyeball for operations upon it. Great differences in this respect are found in practice owing to the site of maximum efficiency for the puncture and counter-puncture in operations for cataract not being the same as for the cut. For this operation Gifford prefers to grasp the internal rectus tendon; he also gives his preferences for various other operative procedures.—A Study of the Etiology of Periodic Ophthalmia in Horses, by Lawrence Post, gives a short account of an investigation carried out in France during an epidemic among the horses of the British Forces in 1916. He concludes that the disease, which is characterised by interstitial keratitis, iritis, and vitreous opacities, is not transmitted by ordinary contagion, as no organism found in the conjunctivæ could be associated with the disease, and aqueous, vitreous, and blood cultures were found sterile.—J. Miltom Griscom, of Philadelphia, publishes a family tree of hereditary optic atrophy. In three generations of 33 persons there are eight males and six females affected and eight males and 11 females unaffected by the disease. Nine affected members have been very carefully examined, and descriptions of the fundus, fields of vision, and X ray appearances of the sellæ turcicæ are given. The reader should consult the original for details.—Other interesting papers are Traumatic Rupture of the Internal Carotid into the Cavernous Sinus, by Isaac Hartshorne; Self-inflicted Eye Injuries, by Marc Landolt; Injuries to the Eye with Report of 1031 Cases, by D. M. Campbell and J. M. Carter; and the Intraocular Foreign Body, by G. S. Derby.

The Optician and Scientific Instrument Maker, May 27th and June 3rd.—In the number dated May 27th Prof. F. J. Cheshire describes a new foco-collimator or apparatus for determining the focal length of any lens system. The usual collimator is a telescope with a system of wires at its focus, and is so arranged that an observer through another telescope, the optical axis of which coincides, can see the cross-wires in its focal plane. In the foco-collimator the system of wires is replaced by a scale subtending a known angle at the principal point of the collimating lens, and from this angle and the size of the image of the scale projected by a lens system the focal length of that lens system can be deduced.

Instruction in geometric optics is given by Mr. W. Swaine in a series of articles of which the third appears in the issue of June 3rd. In this issue also optical problems are propounded by Mr. E. Mayer, the Inverse Problem in Transposition, and optical solutions supplied to the questions of the recent examination of the Spectaclemaker's Company by Messrs. Laurance and Wood. A description is given of a Crookes-glass demonstrator. It is well-known that light rich in ultra-violet rays, passed through a fluorescent fluid such as quinine solution or a fluorescent screen such as is used in radiology, shows through a spectroscope a lengthening at the violet end. The invisible rays are made visible. In this appliance the light produced from a nichrome arc is projected on to a screen of uranium glass and the glass to be tested is then interposed. Its chief merit lies in conveniently providing a source of light rich in ultra-violet rays.

British Journal of Children's Diseases. Vol. XVIII. April–June. Edited by J. D. Rolleston, M.D.—In a paper entitled Some Remarks on the Diagnosis and Treatment of Congenital Syphilis, Dr. C. F. Marshall discusses the ætiological importance of congenital syphilis in affections of the different organs and the chief points in differential diagnosis. In his remarks on treatment, which is considered under the headings of ante-natal and post-natal treatment, Dr. Marshall states that ante-natal treatment, although diminishing fœtal mortality, may lead to an increase in the number of cases of late congenital syphilis. In his opinion combined treatment with mercury and salvarsan given during pregnancy only yields better results than treatment with mercury alone both before and during pregnancy, as regards the number of children born alive and free from symptoms at birth. Salvarsan appears to have little or no tendency to cause abortion when properly administered. As regards post-natal treatment, Dr. Marshall prefers intramuscular injection of salvarsan combined with glucose to diminish the pain to intravenous injection. He has never seen necrosis of the buttock, which has been urged as an objection to this method, and suggests that this occurrence may be due to too bulky injections or to mixture with creocamph. He recommends that mercury should be given simultaneously, either in the form of grey powder or inunction, and continued for a year at least.—In a paper on Diurnal Somnolence and Nocturnal Wakefulness as Manifestations of Lethargic Encephalitis Dr. H. Morley Fletcher describes two illustrative cases in boys aged 9 and 11 years. In his comments on these cases Dr. J. D. Rolleston remarks that nocturnal wakefulness as a sequel of lethargic encephalitis has recently formed the subject of numerous papers emanating from pædiatric and neurological clinics in Germany, Austria, Italy, and Switzerland, the features common to all the cases being the long duration of the symptom, its association with other manifestations of epidemic encephalitis, and the inefficacy of treatment. One of Dr. Morley Fletcher's cases was an example of the ambulatory type of lethargic encephalitis, of which several cases have been reported, especially in children. The nocturnal wakefulness in this case was a symptom, whereas in the second case it was a sequela.—Dr. F. Parkes Weber records a Fatal Case of Emaciation in a Girl at about the Period of Puberty, with General Visceroptosis, Hypotonicity of the Stomach, and Achylia Gastrica. No necropsy was performed.—In a paper on the Treatment of Prolapse of the Rectum in Infancy and Childhood by the Injection of Alcohol, Dr. Leonard Findlay describes a method which he learnt in Prof. D'Espine's clinic at Geneva, consisting in injection of 1·5 c.cm. of absolute alcohol into the submucous tissue on either side of the rectum under an anæsthetic. In 22 cases in children aged from 5 months to 7 years in which Dr. Findlay employed this method practically a complete cure was obtained. In several cases the prolapse returned, requiring a second injection, and in one child a third injection was necessary before a cure was obtained.—Dr. G. Cochrane describes a case of Diphtheria of the Penis with Paralytic Sequelæ, in which a boy aged 3½ years suffered from post-diphtheritic paralysis of a severe type, although the penis had been exclusively affected by diphtheria.—Mr. E. E. Hughes reports a case of Empyema of the Maxillary Antrum in an Infant aged 3 weeks, the condition probably originating in birth injury. Pus was evacuated through an incision in the upper alveolus, and in three weeks complete recovery took place.—The abstracts from current literature are devoted to acute infectious diseases and syphilis.

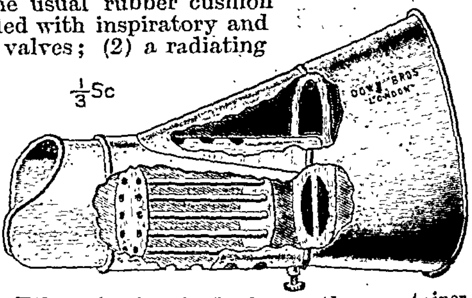
Great Northern Hospital.—The Great Northern H[illegible] Recovery, at Grovelands, Old Southgate, London, [illegible] opened by the Princess Royal, on Saturday, [illegible] at 3 P.M. A summer fête and country fair will [illegible] Grovelands Home Park, from 3 to 11 P.M.

New Inventions.

A COMPACT WARM ETHER INHALER.

The advantages of warm ether vapour for anæsthesia by the open method are generally admitted; they were described by Dr. F. E. Shipway in this country in 1916,[1] and considerable experience was afforded later by the use of his apparatus at many clearing stations and hospitals during the war. A general discussion on the subject took place in the Section of Anæsthetics of the Royal Society of Medicine on April, 14th, 1916.[2] I have, however, felt the need of an inhaler of some kind which, being independent of an extraneous source of heat and not needing continuous air pumping, would be sufficiently compact to be easily accommodated in the anæsthetist's bag, and would yet warm the inspired vapour to a sufficient extent.

This inhaler, in which I have employed the device of utilising the heat of the patient's expired breath, resembles the small Roth-Dræger instrument and consists (see illustration) of three parts: (1) a face-piece carrying the usual rubber cushion and provided with inspiratory and expiratory valves; (2) a radiating chamber containing 19 thin metal tubes; (3) a container for sponge or gauze on which the ether is dropped. Ether is inspired from the container through the warmed "radiator" tubes, while the expired breath is directed by the expiratory valve through a short passage into the radiating chamber where it passes between the tubes, to which it gives some of its heat, and escapes through holes in the opposite side. The radiator is locked to the face-piece by a small screw, and the container can be revolved into any convenient position for the dropping of ether. The inhaler is strictly of the semi-open type, but the air-way has been kept everywhere as free as possible to prevent restriction of breathing and promote interchange of heat; a slight amount of re-breathing is allowed by the volume of the face-piece, the in- and out-going streams being otherwise separate.



Without the radiating chamber in use the temperature of the inspired vapour above the face-piece is from 32° to 38° F. This is considerably lower than is shown by a thermometer under a Skinner's mask during "open" administration; but here the actual temperature is variable and uncertain owing to the fluctuation of the alternate warm and cold streams. On bringing the radiating chamber into use the temperature rises in the course of a few minutes to 65° to 70°, occasionally higher, generally rather above room temperature, and remains fairly steady. This is again not so high as can be obtained with an extraneous source of heat, but is, I think, sufficient for the purpose. There is a considerable economy of ether over the use of a mask, and a welcome diminution in the amount of ether in the air surrounding operato and anæsthetist. Anæsthetic mixtures can be use equally well if desired. The instrument is mad entirely of metal except for the rubber cushion an the valve-flaps; it can therefore be readily sterilised Its length is approximately 7 in. and its weight 13 o

It has been made for me by Messrs. Down Bros. St. Thomas's-street, London, S.E., to whom I am als indebted for the illustration.

St. Leonards. G. A. Ticehurst, M.B., B.C. Camb.

THE LANCET.

LONDON: SATURDAY, JULY 9, 1921.

National Insurance in the U.S.A.

THE question of National Health Insurance is awakening now the interest of the medical profession in America. That it has attracted the attention of such American bodies as would constitute what are here known as Approved Societies was proved by the visit to this country some two years ago of prominent officials of insurance and other similar bodies; but the various problems were at that time being approached rather from the standpoint of insurance than of health. The exposition of National Health Insurance in England by Dr. ALFRED COX, the medical secretary of the British Medical Association, recently published in the *Journal of the American Medical Association*, will therefore be of the greatest benefit to the medical profession in the United States, and it should be read by medical men of all nationalities where the adoption of a scheme of National Health Insurance is contemplated. Critics of the working of the medical benefit clauses of the National Insurance Act in England should also take to heart what, out of full knowledge, Dr. COX has to say on many difficult and contentious points, where comprehension is required before adjustment of difficulties can be advocated.

The National Insurance Act, 1911, was fully debated as regards principles when the legislation was introduced, but too little time was allowed for the working out of details, while defects which originated with haste, have continued, and in some directions have increased. We need only allude to the friction caused by certain of the revised regulations to show how hard has been the path of construction both for the Government and for those upon whom responsibility for working the Act devolves. The new medical record cards, which are assumed to represent each practitioner's correct panel list, fall far short of the assumption, while the information recorded on them is found by some to include too much for professional ethics, and by others too little for eugenic or statistical purposes. This is only an example of the directions in which a vast national constructive scheme may be seen to be tentative, and awaiting addition, revision, or pruning. It is hoped for their sake, and quite as much for our sake, that our American colleagues will be prompt in taking part in the discussions which will be essential if a scheme of National Health Insurance is introduced in the United States. They can learn from the mistakes of their British brethren to avoid many of the things which have been sources of annoyance with us, and which remain to breed discontent. The practitioners in America who may be called upon to work the scheme—the rank and file of the profession—ought to be organised so that their opinions may receive the consideration that will be given to views of reasonable unanimity, if they are reinforced by sound argument, and are directed to the good of the community and not confined to plans for professional security. This is the larger policy, for to obtain good medical service good conditions of work must be present. A hope may also be expressed that financial circumstances in the United States will allow of the formation of a more complete scheme than was possible in this country, with the concurrent upheavals of war. Shortage of money has resulted in our medical profession being the sufferers for many deficiencies in the British scheme. The lack of adequate facilities for institutional treatment, the failure to provide for second medical and surgical opinions, for nursing services, or for laboratory facilities have done much to keep alive the fiction that participation in panel practice is "derogatory." That the financial position has been improved in various directions no one denies, and that the health of the nation has benefited in existing circumstances is equally true; to these items on the credit side must be added the fact that the cost, in so far as sickness benefit is concerned, has been overestimated, as is proved by the recent valuation reports of the Approved Societies. All this indicates that, as time goes on and as experience ripens, our system of National Health Insurance will be found, once the need for such a service has been admitted, to contain the essentials for general success.

No doubt there are many practitioners in the United States, who, when new schemes are put forward, will be found wedded to their present routines of practice, and who will resent any interference with their lives. There will doubtless be also many of the laity who will, as many here do even now, view the services rendered under the National Health Insurance Act with suspicion. It may be assumed, however, that there will also be sufficient doctors able and willing, as here, to remove in time these suspicions —men who, however much they resent the profound changes in the practice of medicine will recognise not only the improvement in their economic position which the adoption of a scheme of health insurance must result in, but will be aware of the greater opportunities offered by such a scheme for the physical benefit of their patients. The Public Health Service of the United States is of excellent quality, the institutions, of which not the least is the Mayo Clinic, are well thought out and organised, and the universities are second to none in the world: provided, therefore, that adequate financial provision is made, there can be no reason why any sound scheme of National Health Insurance which the United States may adopt should not start at a point which we can only hope to reach after many years. We have much to offer in the way of example, while the scheme outlined in the Dawson Report might well form the basis of a complete service in any civilised country. There seems to be in the United States ample time for consideration by all concerned, so that a system may be fairly expected which by its very completeness would disarm criticism, ensure the benefit of the community, and secure the goodwill of the medical profession.

◆

Silicosis.

THE paths of research are tortuous and often lead away into unexpected lands from which the pioneer cannot hope soon to return with what he set forth to seek. Often he finally returns with an entirely different, although, perhaps, an even more valuable commodity. In his address to the Research Defence Society, which we publish on p. 112 of our present issue, Dr. H. H. DALE describes how certain explorers went forth into the wilderness to seek one clad in soft tissues, the tetanus bacillus—and, behold, more than the tetanus bacillus, even the *raison d'être* of tuberculous silicosis, was there. It is almost a fairy story with Pan in the background. Dr. W. E. GYE, in the course of investigations on tetanus, found that the bacilli flourished in the body and caused disease only if introduced together with soil. Next, Dr. GYE in association with Dr. W. CRAMER, discovered that the soil must contain either soluble calcium salts or hydrated soluble silica. Further, injection of either of these substances into mice rendered them sensitive to the disease when inoculated with washed tetanus bacilli which were otherwise innocuous. Here nearly certainly lies the explanation of why on the Western front the prevalence of tetanus varied so much in different parts of the line; it varied with the chemical composition of the soil. At once a vista of a connexion between geology and disease is opened up; and Dr. S. BARWISE's correlation between the prevalence of phthisis in Derbyshire and the geology of the county immediately comes to mind. Here the first chapter may be said to end.

Then suddenly Dr. GYE stumbled upon a hyper-concentrated solution of vital statistics from which only a touch from the experimental wand was needed to precipitate clear crystals of knowledge. The work of Dr. J. S. HALDANE upon dust inhalation and the statistical evidence placed by Prof. E. L. COLLIS before the Royal Commission on Metalliferous Mines and Quarries, which is summarised in his Milroy lectures, had established definitely that silica alone among dusts possessed the peculiar power of sensitising to tuberculosis those who inhaled it over long periods. Even as GYE was at work COLLIS,[1] who for years has opposed the old accepted theory that mechanical irritation following upon dust inhalation was the cause of dust-phthisis, and has pointed out that this theory was incapable of explaining why the disease only occurred among those inhaling silica dust and not among those inhaling other equally hard and irritating particles, such as emery, was writing: "Theory rather suggests that when silica is introduced into the body some definite chemical reaction should occur . . . a reaction which results in the formation of fibrous tissue, now known pathologically as silicosis. Lungs so damaged fall a ready prey to the tubercle bacillus." Dr. GYE had sensitised mice to tetanus with silicic acid. What about tubercle, to which these animals are normally immune? After experiments in association with Dr. E. H. KETTLE, he is now able to announce that silicic acid (and even silica dust) also sensitises these animals to tubercle, which spreads in the tissues injured by the silica. We have then only to conceive that silica dust when introduced into the body slowly undergoes conversion into silicic acid to understand the ætiology of tuberculous silicosis; and W. WATKINS-PITCHFORD has pointed out that inhaled particles of silica do so disintegrate in the lungs. Nor is further evidence lacking: for mice injected with silicic acid suffer from nephritis, while COLLIS has noted that in occupations, such as tin-mining, dressing sandstone, and grinding cutlery, where tuberculous silicosis is rife, the mortality from Bright's disease is high. The conclusions to be drawn are that fine particles of silica, derived from flint, sandstone, quartz, or gradually undergo conversion in the body into soluble hydrated silica; that this substance as formed acts locally on the tissues in the vicinity, giving rise to fibrous new growth, possibly even stimulated to do this by the presence of tubercle bacilli which, WATKINS-PITCHFORD has pointed out, will precipitate latent silicosis; that tuberculous infection finds in such silicotic tissue a favourable nidus for growth; and that any soluble hydrated silica which gains access to the blood stream is excreted by the kidneys which are affected by it.

These fresh conclusions come when research has hardly yet familiarised us with the ideas that in the treatment of phthisis the value of cod-liver oil and other animal fats depends upon the presence in them of the food accessory factor, fat-soluble A; and that, envisaged from this aspect, phthisis may be regarded as disease occurring among persons sensitised by dietetic deficiency. Now we learn that sensitisation may also result from an inorganic poison. Simultaneously another member of the Medical Research staff, Dr. LEONARD HILL, is attacking the problem from another side by establishing the way in which health and vigour, needed to resist disease, can be increased by increased metabolic activity brought about by stimulating atmospheric conditions. In each case the problem of tuberculosis is being removed from the bacteriological laboratory to that of the biochemist in association with the morbid histologist. Only time and further research can reveal how the flood of light, shed by new knowledge on the way in which the human body may be sensitised to the tubercle bacillus or protected against it, can be put to immediate practical use for preventing tuberculous silicosis in those industries in which it prevails. The recent inclusion of the disease under the Workmen's Compensation (Silicosis) Act, 1918, as one for which compensation must be paid (as the industries concerned are one after another brought by order of the Secretary of State under the provisions of the Act), gives immediate financial importance to such an aspect of the case in this country. In South Africa the financial side of the question has long been apparent. If, in the light of the new knowledge, means can be devised to abolish the disease, a financial burden will be lifted from industry far exceeding the whole sum devoted to-day to medical research, while a scourge will be removed from certain occupations which has clung to them through the ages since man began to make for himself instruments from flint or to dress sandstone for building purposes.

Freudism in Medicine.

THE place of psycho-analysis in the equipment of the practitioner of medicine demands attention. Though few medical men past middle age can swallow the new psychology whole without symptoms of indigestion, culminating, it may be, in spiritual if not physical nausea, the younger generation is imbibing the newer ideas with avidity. In the past the psychologist has taken his samples for analysis from the surface of an apparently clear stream, in the belief that it was sufficiently representative of the water as a whole. The moderns scrape up mud from the bottom, if necessary displacing the filtering stones to secure it. To the onlooker this method would seem no better than the first, and, moreover, it leaves the stream very muddy. Nevertheless, in the light of the experience now being gained, future psychologists, made wiser through the errors and omissions of their predecessors, may be enabled to estimate the practical importance of traces of sediment contained in the preliminary sample, delving deeper only when circumstances demand it. At the moment it is mainly the recently qualified medical men and women, with a sprinkling of medical students, who are keenly interested in psycho-analytical methods. The epidemic form of psycho-analysis to which certain sections of medical students have fallen victim owes its existence partly to the feeling—possibly an illusion—that by submitting to analysis the student is preparing himself on the broadest lines for a medical career; it may partly, and unknown to him, have a different origin. But, manifestly, the gap between medicine and the later developments of psycho-analysis is so wide that at present only the more elementary presentations of psycho-analytical ideas are intelligible on the surface. We must not for this reason allow a whole method of therapeutics to slip out of our grasp.

[1] Effect of Dust Inhalation upon the Incidence of
ublic Health, March, 1921.

There are two main difficulties in accepting FREUD's theories. The theory of the unconscious explains conduct as arising from motives, and even trains of thought, which are not apparent to consciousness or under its control. Psychologists had prepared the way by showing how we are ruled by instinct and emotion; yet the personal application of this theory of the unconscious, with its seeming dethronement of reason, is repudiated by our common sense, which tells us that we know, or ought to know, the reasons for all our actions, and that conduct is based upon rational motives derived from the principles of conscious pleasure and pain. The second difficulty lies in FREUD's view that infantile psycho-sexual development has influence not only upon the psycho-neuroses but upon ordinary inclinations and desires. To this difficulty many factors contribute, one of the chief being the confusion between sexual activity and action urged by the sex instinct; the first is unusual in an infant, the second may be usual in all infants. The difference between the views of FREUD and JUNG are well known. FREUD, whilst admitting the existence of other instincts, finds the sex instinct predominant in influencing life and character, and regards the unconscious working of that instinct, with its many ramifications, as the foundation of the psycho-neuroses. JUNG regards the driving force of mental life, the libido, as the mainspring of good and evil; a wrong mental attitude, traceable to difficulties in childhood and often first appearing at that time, hinders adjustment, and the libido, checked in its natural outlet but still demanding satisfaction, turns to the production of the neurotic symptom as a means of finding it. To JUNG sex is only one manifestation of the libido, but is so all-pervading that the libido makes great use of it as a means of expression. JUNG claims to find, behind the sex mechanisms described by FREUD, a misdirection of libido expressed in the neurotic symptom. He also finds in the symptom, as in the dream, indications of the striving of the libido and of the direction in which it should seek an outlet. Hence he claims to be more constructive than FREUD. The time has come when the practitioner must take a serious interest in these considerations, unless he is to lose touch with the more thoughtful section of his patients, for their influence on the lay public is widespread.

A letter appears in another column from that wise physician and experienced man of affairs, Sir BRYAN DONKIN, which we hope will be read carefully. It is not in agreement with the views expressed above, but it proves how necessary it is that those who are working along the lines of FREUD should temper their zeal with discretion, should appreciate at what point they desire to leave the old course, and should be able to show their reasons for so doing, in order to give proper attribution to any successes with which they may meet. The methods of experimental psychology will never be deserted, but assistance to our therapeutics must not be refused because it does not arise directly out of such methods. On the other hand, we have a right to ask that the theories, precepts, and claims of psycho-analysis should continue to undergo rigorous scrutiny; for psycho-analysis is a new acquaintance, not an old and well-tried friend.

◆

M.O.H. REPORTS.

MOST of the annual reports of medical officers of health commented on in THE LANCET hold strong resemblances in certain particulars. The general death-rates and infant mortality-rates for 1920 are low, frequently the lowest ever recorded. There was a widespread increase of mortality from tuberculosis of the lungs during the war, but it is surprising to find that not only has this war increase disappeared, but that the death-rates are now lower than ever before, at a time when overcrowding is general. It is doubtful if the war increase and the subsequent decline have been properly explained. The usual explanation is that the increase was largely industrial; men and women who were not inured to factory life broke down under the strain, their age or state of health perhaps unfitting them for the work they attempted. On the other hand, it is notorious that many women who worked in factories apparently improved in health owing to provision by canteen of much more sensible dietary than they were previously accustomed to. On the whole it may be said that during the war the working man, woman, and child had a more plentiful dietary than usual. Children among the poorer sections of the community were better clothed and apparently better fed; they had less sugar, but made up for it with more starch. The question arises as to whether the greater tendency to consumption resulted from the quality of the food—i.e., the scarcity of the right kind of fat. Research on vitamins emphasises the importance of butter, suet, dripping, egg yolk, and cod-liver oil in preventing rickets and securing good teeth. The past reputation of cod-liver oil as a remedy for tuberculosis and its extraordinary richness in the fat-soluble A vitamin naturally suggest that its value in this direction may be due to its vitamin content, and that scarcity of the other fats which are plentifully endowed with this vitamin may have played a part in the war increase of tuberculosis; a better supply of these fats has been available since the end of the war. It has also been suggested that a large number of tuberculous persons died in the influenza epidemic, and that the present low death-rate is only temporary. A rise is perhaps unavoidable if overcrowding continues to increase in the present geometrical progression resultant upon our inability to build houses to accommodate the natural increase of the population. The effect of education of the public by means of tuberculosis dispensaries and other health agencies must not be ignored; moreover, the recorded experience of many, if not most, tuberculosis dispensaries, is that consumptives escaped influenza in a remarkable manner, perhaps because they led a more or less open-air life, and avoided crowded rooms. The incidence of tuberculosis during and since the war has not been satisfactorily explained, and offers a field of investigation to statisticians with a knowledge of public health.

THE Right Hon. F. B. Mildmay, M.P., has been appointed a member of the Medical Research Council, in succession to the Hon. Edward Wood, M.P. Mr. Mildmay will act as Treasurer to the Council.

Annotations.

"Ne quid nimis."

MEDICINE IN EVOLUTION.

THE learned Professor of Physic in the University of Cambridge, Sir Clifford Allbutt, in a volume of essays and addresses,[1] which has appeared this week, illustrates in a remarkable way, though the book has no such design, that the story of medicine is one of evolutionary progress, the progress having been held-up by world events in this or that direction, to re-take or re-shape its course, quickly or slowly, but always advancing. The first half of the book consists of the FitzPatrick lectures, delivered before the Royal College of Physicians of London in 1909–1910. The lectures, however, have been considerably enlarged, as anyone will see who refers to their original publication in our columns, and they have appreciated in interest and value in proportion to the enlargement, which is an unusual circumstance in work of a scholarly and serious nature. Time after time the learned address, as delivered, is greatly improved in force and directness by abridgment, but in the case of Sir Clifford Allbutt's FitzPatrick lectures it is good to possess not only the original words, but also a great deal of the documentary background. Sir Clifford Allbutt once likened medical history to a geological record, but he now prefers to compare its noble fragments to a basilica compiled of more ancient relics—of pillars, of capitals, wrought stones, and mosaic, gathered and built into a new edifice. "We have thrust ancient myth and symbol too much aside as wholly fanciful: we are discovering now that they are apparitions, luminous mists of truth—the edges and bordering lights growing in form from one incarnation to another."

The subject of the FitzPatrick lectures was primitive Roman medicine in relation to the medicine of Greece, and over the whole of this field Sir Clifford Allbutt displays a wide range of erudition and an intimate acquaintance with the writings of other historians, while his position at Cambridge has enabled him to obtain assistance on particular points from such authorities as Prof. Henry Jackson, Prof. J. S. Reid, Mr. Bernard Cook, and Sir John Sandys. While the Roman Empire held the political supremacy, Athens, in almost all the higher ranges of the human mind, was still supreme, says Sir Clifford Allbutt. He refers to the address of the late Dr. Warde Fowler, president of the Classical Association for last year, in which that charming and polished scholar and naturalist—now, alas, passed from us—deprecated the common idea that the Romans lacked imagination as compared with the Greeks. Sir Clifford Allbutt fears in his pages that "Mr. Fowler will see but evidence the more of that conventional depreciation of the Roman in comparison with the Greek"; but he appeals for extenuation inasmuch as he has had to deal with a side of the Roman mind in which that great people was deficient. Medicine at Rome was, of course, Greek, and consequently such superior persons as Cato and Pliny, who looked down upon everything Greek, looked down also upon medicine and medical men, a very similar view being taken in Italy some thousand years later by Petrarch. The remainder of the book is a series of essays and addresses upon such varying subjects as Byzantine medicine; mediæval medical learning, illustrated by the position of the ancient University of Salerno; the growth of hospitals and the development of public medical service; medicine in the fifteenth century and at the beginning of the nineteenth century; and Palissy, the savant and potter.

The book is frankly an assembling of scattered essays and addresses, but every word is written in support of the thesis that medicine steadily evolves towards scientific wisdom and truth.

THE IRREGULAR INCIDENCE OF PLAGUE IN INDIA.

PLAGUE, as our readers are aware, has been annually epidemic in India since 1896, but the incidence of the disease during that period has been very unequal, some provinces, like the Punjab, having had devastating epidemics year after year, while others, like the Presidency of Madras, have experienced comparatively light local manifestations of the malady, while yet others, like Assam, may be said to have escaped almost entirely, notwithstanding repeated importations of the disease from other heavily infected provinces. Various explanations of this unequal distribution have been advanced from time to time. Up to the present the explanation which found most acceptance was that the small incidence of plague in some provinces was due partly to the manners and customs of the people, and partly to the fact that the nature of the construction of their dwellings did not favour infestation by rats. Meanwhile the subject for some time has been undergoing investigation, particularly in the Presidency of Madras, in which the various conditions have been carefully studied and compared with those in other provinces, but so far without any convincing results.

A new hypothesis, however, has been put forward recently by Major F. W. Cragg, I.M.S., Assistant Director, Central Research Institute, Kasauli, in a contribution published in the lately issued Special Indian Science Congress number of the *Indian Journal of Medical Research*, in which is discussed the distribution of the Indian rat-fleas of the genus Xenopsylla, with reference to the immunity of certain areas from plague epidemics. It appears that the Plague Commission during the whole period of their inquiry recognised only one species of the genus Xenopsylla—viz., *X. cheopis* on Indian rats, and until recently this flea was universally regarded as the predominant species infesting rats in tropical and sub-tropical climates. At least two other species of Xenopsylla, however, are found in India—viz., *X. astia* and *X. brasiliensis*. The differentiation of the species is not easy, requiring the use of a compound miscroscope and a fairly high power. It is by no means the case that all species of fleas, even those of the same genus, are necessarily equally efficient as transmitters of the plague infection. One important factor which may vary with species is the degree of readiness by which the species adopts man as a host in the absence of its normal one. It has been shown experimentally that all fleas are not alike in this respect. A species of rat-flea which is reluctant to bite man, and which perhaps prefers some other animal when its normal host is unavailable, is not likely to be a serious factor in the spread of plague. The length of life, rapidity of reproduction, and the duration of the early stages are all closely dependent on conditions of temperature and humidity; but, according to Major Cragg, the optimum conditions are not the same for all fleas. The powers of resistance to unfavourable conditions, such as extremes of heat and cold, lack of food, and so on, all affect, to some extent, the importance of a species as an agent in the diffusion of plague, and this capacity may be expected to vary in different species. The probability of there being several species of the genus Xenopsylla, each with its own optimum conditions, and each, perhaps, having from various causes a different degree of effectiveness as a transmitter of plague, has not hitherto, it seems, received due consideration. In the *Journal of Hygiene* (Vol. XV.) W. M. Philip and L. F. Hirst, in a report on plague during 1916 in Ceylon, stated that the predominant rat-flea in Colombo was *X. astia*, which they point out bites man with reluctance at temperatures above 80° F., and it rarely attacks the guinea-pig, which animal, it may be remembered, was used by the Plague Commission as a trap for rat-fleas at Bombay. It is said that in Ceylon actual transmission of plague from rat to man by *X. astia* was carried out with the greatest difficulty. The infecting organism at Colombo was highly virulent, the human and the rat population were susceptible, and both rats and their fleas were sufficiently numerous; but yet notwithstanding the presence of all these factors the incidence of plague in man was comparatively little, the relative inefficiency of *X. astia* as a carrier of plague being regarded as one of the possible causes of the failure of the malady to spread in Ceylon. It may be mentioned that W. M. Philip and L. F. Hirst made a collection of rat-fleas from various areas, and those obtained from Madras city (where plague has practically never spread though often imported into it), all proved to be *X. astia*. Major Cragg, therefore, concludes that if the predominance of this species of flea on the Ceylon rats is associated with a low plague incidence there in man, it is probable that the plague-free districts of India may owe their immunity to the predominance in them of this same species of rat-flea. Accordingly, with a view to decide the point, Major Cragg has obtained the coöperation of the Sanitary Commissioner with the Government of India in the carrying out of an investigation into the identity and distribution of the species of rat-fleas predominant in the various districts of India, and for this purpose he has secured the assistance of a number of civil surgeons, health officers, plague officials, and others in different parts of India. The inquiry, we understand, has only been in progress for about two months, and it is therefore too soon as yet to expect any definite conclusions. It has, however, been found so far that *X. cheopis* is the predominant species in the cooler parts of India and *X. astia* in the warm and damp regions. On the other hand, *X. brasiliensis* is not common; it has only been found at Poona, Mangalore, Bombay city, and Ootacamund. Major Cragg intends to find out the distribution of each of the species of Xenopsylla and their seasonal prevalence. Should *X. astia* prove in fact to be the rat-flea of the immune areas in India, he will test experimentally its effectiveness as a carrier of plague as compared with *X. cheopis* and under varying climatic conditions. If it should be shown experimentally that *X. astia* can act as a carrier of plague to any degree, it will become necessary to investigate its life-history and bionomics in order to explain why it does not act as such in nature.

---

[1] [illegible] in Rome: the FitzPatrick Lectures for [illegible] Historical Essays. By the Right Honourable [illegible] Allbutt, K.C.B., M.D., F.R.C.P., Regius Professor [illegible] University of Cambridge. London: Macmillan [illegible]

These systematic investigations may, in one way or another, throw light on some of the problems of plague which still baffle the epidemiologist.

THE OCULO-MOTOR NUCLEI AND THEIR TRACTS.

BRITISH ophthalmic surgeons recently have directed a good deal of attention to problems connected with the oculo-motor nuclei and their tracts. At the Oxford Ophthalmological Congress last year Mr. Richardson Cross took as the subject of the Doyne Memorial Lecture the Nerve Paths and Centres Concerned with Sight," and gave a very full and clear account of the human and comparative anatomy of the parts. Last March the Neurological and Ophthalmological sections of the Royal Society of Medicine held a joint debate[1] covering much the same ground on the neurological aspect of which we commented at the time. The introductory papers to this debate by Dr. Gordon Holmes and Mr. Leslie Paton, which appear in full in the June number of the *British Journal of Ophthalmology*, deserve careful study from the ophthalmological point of view. Mr. Paton divides his paper on ocular palsies into two parts, (1) anatomical; (2) clinical. In the anatomical section he gives a clear digest of the facts known regarding the position, inter-relations, and functions of the nuclei of the third, fourth, and sixth nerves, and discusses the views that have been advanced as to the distribution within the nuclei of the various muscle groups. Very diverse views are held, for example, as to the position in the third nerve nuclei of the cells concerned in the innervation of the sphincter pupillæ. The text-book description, based on Bernheimer, places them in the small-celled mesial group at the anterior end of the nucleus, but much of the recent work done has failed to confirm this, and Magitot actually suggests, in support of Gaskell's theory, that sphincter control is not a function of the oculo-motor nucleus at all, but, through the continuation upwards of the intermedio-lateral tract of the cord, of the sympathetic system. A good account, illustrated with diagrams, is given of the posterior longitudinal bundle, that puzzling but important tract wherein lies the mechanism of association of the whole ocular system. The vascular supply is also discussed in detail and the significance of the supply of these nuclei by end-arteries is emphasised. In the clinical part a full classification of ophthalmoplegias is attempted, and certain typical examples, illustrative of particular groups, are described in some detail. Encephalitis lethargica is taken as an example of infective ophthalmoplegia, and Mr. Paton draws attention to the correspondence between the eye muscles affected in this disease and those which get out of control, as it were, on falling into ordinary sleep. Failing accommodation, dilating pupils, difficulty in convergence, and ptosis, as well as unconsciousness, are common to both states. The three types of lesion revealed microscopically in this disease congregated, as a rule, in the region of the aqueduct of Sylvius, are well described, and this section furnishes ophthalmologists with a good summary of this new disease.

Dr. Holmes's paper is entitled "Palsies of the Conjugate Ocular Movements." He gives a good description of the cortical centres and of the stream of peripheral stimuli that maintains their tonic activity. The evidence for the centre in the second frontal gyrus in man and animals is detailed. It is well known that irritative lesions in this area cause clonic conjugate movements of the eyes to the opposite side, and paresis of the mechanism of voluntary lateral deviation has also been described after war wounds. Dr. Holmes concludes there is no evidence of an oculo-motor centre in the parietal lobe (angular gyrus) in man, but he has observed ocular apraxia without associated disturbances of spatial orientation to follow gunshot wounds in this neighbourhood. He considers the conjugate eye movements obtained by Schäfer through stimulation of the visual area in the occipital lobe, to be reflexes arising from a desire to fix the eyes on the point in space to which the cortical sensations induced by the stimulation are projected. He regards the visual cortex as a higher ocular reflex centre as well as a perceptive area, and believes that movements other than willed and purposive ones, such as those by which the eyes follow a moving body or those by which objects perceived in the periphery of the field of vision are brought into central vision, are effected through it. The paretic deviation towards the seeing side in hemianopia can thus be explained as due to loss of visual impressions that normally excite reflex activity. The question of paralysis of the conjugate lateral movements of the eyes is very ably discussed. This symptom is associated with disease in the lower and dorsal part of the pons, especially near to the abducens nucleus of the same side. Both abducens and oculo-motor nuclei are involved, and the origin of the fibres in the posterior longitudinal bundle, conveying the impulses that excite conjugate lateral movements, has been investigated. Dr. Holmes inclines to the view that a supranuclear centre exists, and gives the evidence in its favour. The last section of the paper discusses paralysis of the vertical conjugate movements and the conclusion is reached that supranuclear mechanisms are present here also. Dr. Holmes supposes the existence in the upper end of the midbrain, at a higher physiological level than the oculomotor nuclei, of "a more complex associational or coordinating mechanism which receives all the impulses that can effect vertical or convergent conjugate movements of the eyes, combines and correlates them into an appropriate resultant, and distributes this to the nuclei of those muscles that should contract or relax." This view is undoubtedly the simplest explanation of all the facts and the mechanism postulated would correspond to the intercalated neurone in the cord between the afferent reflex fibres and the motor cells of the ventral horns.

---

[1] THE LANCET, 1921, i., 748.

ANTARCTIC BACTERIA.

Sir Ernest Shackleton's prospective visit to the Antarctic has revived interest in the conditions of any form of life in these fascinating regions. It might well be supposed that active manifestations of bacterial life would be impossible under the inhospitable conditions of Antarctic glaciation and at temperatures which rarely rise to freezing point. The researches of more than one observer, however, show that such a supposition is erroneous. Dr. A. L. McLean, who accompanied Sir Douglas Mawson's Australasian Antarctic expedition, is the latest to publish[1] the results of his bacteriological observations, carried on during the three years preceding the war, and they serve to confirm those of previous workers in this field. It is astonishing to find that the snow and solid ice covering the Southern Continent are by no means destitute of bacterial life. Portions of ice collected, with strict precautions, not only on the surface but at a depth of many feet, were found to contain living bacteria of various kinds; motility was observed on thawing and successful cultures were obtained. It is conjectured that the strong current of air which is known to flow at great altitudes from the Equator to the Pole, carries with it from warmer regions not only dust particles, but living bacteria, which ultimately become precipitated upon the polar ice-cap. Dr. McLean collected falling snow in a sterilised vessel, and proved it to contain living organisms. It has long been known from laboratory experiments that no degree of cold yet attained will kill bacteria, but it might well be thought that they must remain dormant when embedded in glacier ice. At very low temperatures this is doubtless the case, but the structure of such ice, first elucidated in the Alps and confirmed by Antarctic observation, indicates conditions under which bacterial growth seems possible at temperatures some degrees below freezing point. For when water freezes crystals of pure water are formed, and any salts in solution remain in the residual fluid, which thus comes to have a lower freezing point, and when this is reached the process is repeated. Thus glacier ice comes to consist of a mosaic of pure water crystals, separated and permeated by channels containing saline and organic impurities. At a sufficiently low temperature the whole is a solid block, but as the melting point is approached the channels reopen and the ice takes on a granular structure. It is in these channels that bacteria appear able to grow even when the temperature is below freezing point. If they can thus maintain their existence in ice, it is not surprising to find that bacteria are present, in the Antarctic, in sea water, in the mud of moraines, and in the ooze from the sea bottom: Dr. McLean found them in ooze from a depth of 300 fathoms. The nature and properties of these organisms could not be worked out in detail, but when we remember that the bacteria of air, water, and soil have received little attention even in temperate climates in comparison with those of the animal body, we shall not think it any discredit that the descriptions do not often allow us to place the organisms with any certainty in our schemes of classification. Nothing indeed was possible, under the arduous conditions in which the work was carried on, beyond noting morphology, Gram-staining, and rough cultural characters.

When we turn to the bacteriology of the animals inhabiting the Antarctic, we are on more familiar ground. Dr. McLean made large numbers of cultures from the intestines of mammals, birds, and fish. In some cases negative results were noted, and it appears that the intestine, in these regions, is definitely poorer in bacteria than is the case in warmer climates, though intestinal worms and external parasites were numerous. Nevertheless bacteria were commonly present, and it is interesting to note that a Gram-negative, sporing bacillus was grown from the intestine of a fish trawled from a depth of 1700 fathoms. Seals furnished consistently positive results, yielding coliform and other organisms. It is noteworthy that pus from the wounds which these animals receive in fighting amongst themselves was found to contain staphylococci and streptococci of familiar types. Dr. McLean's report leaves us with an increased respect for the pertinacity and versatility of bacterial life under the most unfavourable conditions, and with no less admiration for the perseverance with which, under conditions hardly less unfavourable, he contrived to make so many interesting observations.

CÆSAREAN SECTION: TWENTY-ONE YEARS' EXPERIENCE.

IN the Jerome Cochran lecture read before the Medical Association of the State of Alabama, Dr. J. Whitridge Williams[1] gives the following analysis of 183 Cæsarean sections performed upon 145 women in the Obstetrical Department of the Johns Hopkins Hospital from Feb. 1st, 1899, to the end of December, 1920. The operations were done on a series of approximately 20,000 deliveries, so that their incidence was somewhat under 1 per cent.; 104 were single and 79 repeated sections. Although the number of white and black women in the service was practically the same, many more Cæsarean sections were done upon the latter. The following types of operations were done: 121 typical conservative sections; 4 extra-peritoneal sections; 1 post-mortem section; 57 Porro sections. The gross mortality was 5·46 per cent., which was reduced to 3·45 per cent. after deducting the cases in which death was not due to the operation. All the deaths except one from hæmorrhage were due to infection. The mortality was 13 times greater in the first 50 than in the last 133 cases—10 to 0·77 per cent., the diminution being due to the avoidance of ascending infection by operating before the onset or during the first hours of labour. Contracted pelvis was the indication for interference in nine-tenths of the black women and in six-tenths of the white patients. The several varieties of rachitic pelvis afforded the principal indication for operation in the blacks, as compared with the simple flat pelvis in the whites. The most frequent non-pelvic indications were eclampsia and severe cardiac decompensation. On the other hand, Dr. Williams does not regard Cæsarean section as the ideal treatment for eclampsia, and considers that it is indicated only in the rare instances in which the cervix is rigid and undilated and no improvement has followed venesection. In only one case, which proved fatal, was the operation performed for placenta prævia, although 66 examples of this complication of pregnancy occurred in this series. Dr. Williams is of opinion that the frequency of rupture of the uterine cicatrix is probably exaggerated, as this occurrence took place only once in 48 women who had undergone repeated sections, as well as in 12 deliveries through the natural passages subsequent to sections. Although it is generally stated that the child delivered by Cæsarean section is born in an apnœic condition and is sometimes deeply asphyxiated, over half the children in the present series cried immediately after delivery, and only 7 per cent. were deeply asphyxiated. Dr. Williams concludes by saying that though Cæsarean section is frequently the easiest manner of delivering the patient, in the presence of various abnormalities it is not always the safest, and that ideal results are obtained in only a few clinics.

JUBILEE OF PROFESSOR LÉON FREDERICQ.

At the end of the present academic year Léon Fredericq, Professor of Physiology in the University of Liége, will become Emeritus Professor on resigning a chair which he has held with high distinction for 42 years, for he was the immediate successor of Th. Schwann. The occasion will also mark the fiftieth year of his academic activities as well as the fiftieth anniversary of his promotion to the degree of "Docteur en Sciences Naturelles." Prof. Fredericq's scientific activities have ranged over a wide field of physiological investigation and discovery, and his name and the results of his life-long work find a place in every text-book of physiology and every physiological laboratory. His wide knowledge of zoology and on occasion its practical pursuit enabled him to take a comprehensive view of physiology. His work ranges over such diverse fields as coagulation of blood and fibrinogen, hæmoglobin and hæmocyanin; physiology of the squid, echinus, and crustacea, autotomy, cardiography, venous pulses, the physiology of the heart and respiration and the cardiac nerves, tension of blood gases, apnœa, variations of the volume of the brain, &c.; while he has added considerably to physiological technique, as in the description of the œsophageal sound, crossed circulation, atriotome, oxygenograph. Moreover, he has trained and helped a large number of pupils to carry out original work in his laboratory, the later results being published from 1888 in the *Archives Internationales de Physiologie*, edited by Fredericq and Heger (of Brussels). His "Éléments des Physiologie Humaine," edited jointly with M. Nuel, is in its seventh edition. It is proposed to publish a "Volume Jubilaire," to consist of contributions by his Belgian colleagues, and those of allied and neutral countries. The volume will be dedicated to Prof. Fredericq and will be published in the *Archives Internationales de Physiologie*.

STEREOSCOPIC VIEWS OF THE MIDDLE EAR.

In the course of an investigation extending over many years Mr. Arthur H. Cheatle assembled the most complete collection of specimens ever made to illustrate the surgical anatomy of the middle ear and of its accessory air sinuses. Every specimen was obtained from a subject of known age and sex, and hence the collection is of the utmost value for the study of the age changes undergone by the middle ear, and of the prevalence in adults of variational types. Ten years ago Mr. Cheatle presented his entire collection to the Royal College of Surgeons of England, where it has been placed in the upper gallery of Room 11 of the Museum, side by side with the famous Toynbee collection. A descriptive catalogue, prepared by Mr. Cheatle, has been published by the College for the use of visitors, who come to study from all parts of the world. There are, however, many aural surgeons and others who cannot afford the time or means to visit London and share in the fruits of Mr. Cheatle's toil, and hence have suggested that stereoscopic views of the more typical and important specimens should be made and placed on the market. This has now been done under Mr. Cheatle's supervision.[1] About 200 specimens have been photographed and a series of lantern slides prepared to meet the needs of those who have to teach the surgical anatomy of the temporal bone. The photographs and slides are of excellent workmanship, and should prove of the utmost utility for teachers of anatomy and aural surgery.

A TRIBUTE TO DR. ADDISON.

Lord Carson presided at the recent complimentary dinner to Dr. Christopher Addison, the late Minister of Health. The gathering was an eminently appropriate one, for political circumstances appear to have dictated Dr. Addison's withdrawal from office at the very time when the value of his pioneer work was becoming evident to all except impassioned critics. It had no political complexion, and was a spontaneous expression of friendship towards Dr. Addison, arising out of his strenuous work in high official capacities throughout the war. Lord Carson said, "Dr. Addison is one of the few who has lasted from the beginning of the war until to-day," adding that he, Lord Carson, had tried to do so, but had failed. Tributes of appreciation to Dr. Addison were paid by Sir Henry Birchenough, Sir Thomas Neil, chairman of the Consultative Council on Health Insurance Societies, Professor R. A. Bolam, chairman of the Council of the British Medical Association, and Sir Ernest Moir, lately Controller of the Inventions Department of the Ministry of Munitions. The dinner was attended by members of both Houses of Parliament and by the staffs of the Ministry of Munitions and of other Departments over which Dr. Addison had presided, and the guest of the evening had a right to be deeply gratified with such multifarious recognition of his patriotism, industry, and zeal.

THE FÆCES IN ALIMENTARY DISORDERS.

The examination of the fæces has not yet become established as an essential part of the clinical investigation of a patient suffering from disease or disturbance of function in the digestive system in the routine way that the urine is observed in morbid conditions of the kidney and in diseases of metabolism. This is the more surprising when it is recognised what valuable indications, both in regard to diagnosis and treatment, examination of the fæces can afford, and, further, how comparatively simple the essential processes in this investigation are. The subject is dealt with in a practical, interesting, and suggestive paper, published in The Lancet of July 2nd, by Dr. Robert Coope. He commences his paper with the statement that it is important to bear in mind that normally on a digestible diet the only food residues found in the fæces are remnants of muscle fibre and the tough débris of vegetables. This fact is often forgotten or not appreciated. It should, moreover, be recognised that test diets may be given, especially where it is desired to examine for occult blood or soluble albumin. Dr. Coope suggests that a simple technique should involve the macroscopical, microscopical, and chemical examination of the fæces, each of which may give valuable information. Such investigation may afford indications of crucial importance, as Dr. Coope's records show. He points out that the abnormal findings can be divided into two catagories: the absence of normal constituents, and the presence of abnormal ones. In the first stercobilin is the chief constituent studied. If it is absent, it may be inferred that no bile is reaching the intestine. In the second category he mentions the presence of various food residues, especially undigested muscle fibre, connective tissue, starch grains, and fat, and the addition of blood, soluble albumin, and mucus. Dr. Coope maintains that if connective tissue reaches the fæces in any marked amount, the conclusion that there is a failure of gastric digestion may be drawn with complete confidence—a practical point. The whole paper is a valuable contribution to the study of diseases of the digestive system. Until recently there was a tendency to treat these diseases in this country in a less scientific fashion than is the custom on the Continent and in America, but the routine application of test-meals, X ray examinations, and fæcal investigations seems likely to become established. The alimentary system admits of more direct investigation than some other of the important systems of the organism, and accurate diagnosis, with effective treatment, should be possible in a large majority of cases.

THE POSITION OF INTESTINAL COILS.

Dr. A. C. Guillaume in *La Presse Médicale* of June 15th has tried to answer the old query as to whether there is or is not any definite arrangement of the coils of small intestine within the abdomen. Nobody would deny that great importance might be attached to a definite answer in the affirmative, but no anatomist will be tempted to give this. Dr. Guillaume's views are in strong support of those usually taught in this country, that the first portion of the mesenteric gut generally lies to the left of the middle line, the succeeding coils being in front and in the pelvis. He points out that the arbitrary junction of jejunum with ileum is fairly constantly placed at the left pelvic brim. English anatomists will agree with these findings and will correlate them not only with the line of mesenteric attachment, but with the greater depth of the mesentery in the region of the ileum; but they will hardly feel inclined to agree with the suggestion that it might be possible to go, with any practical advantage, into more particular details of topography. It may be admitted at once that the material on which the anatomist works is not typical of young and healthy bodies, but in spite of that, and perhaps even on account of that, it represents a class likely to come under clinical observation and to call for clinical diagnosis. Yet even the anatomist who is accustomed to open these bodies hesitates to predict what he will find in the abdomens. Treves, Henke, Sernoff, Weinberg, and other investigators have reached divergent conclusions regarding the arrangement of the coils of the small intestine. Mall's primary loops are of developmental interest, and are recognisable to a great extent in the adult, but hardly bear on the present question. The situation of coils en masse, and also their disposition and direction, would seem to be related in some way to the arrangement of the large gut, but no definite laws on this matter have yet been laid down; the point is not dealt with by Dr. Guillaume. His work is of some interest to the clinician, but more observations will be necessary to establish the proportionate occurrence of the varieties he gives and to indicate the conditions concomitant with these varieties, so that the chance of an error in topographical intestinal diagnosis may be reduced to an absolute minimum—and this, we fear, will remain an ideal for many years to come.

THE SIROCCO FAN.

Sir Samuel C. Davidson who received the K.B.E. on the occasion of the visit of the King and Queen to Belfast is not indeed a medical man, but he has done a great deal for hygiene, particularly at sea. He is the inventor and manufacturer of the "Sirocco" fan which, first invented to dry tea, is now used so extensively, particularly in the ventilation of ships. There are at least 68 in the *Aquitania* and 74 in the *Olympic*, more likely 100 in each, but we may say, without fear of serious inaccuracy, that every large steamer uses them for forcing draught in the stokeholds; they are employed in the Royal Navy, while one of the tube railways and one well-known theatre are ventilated with their help. The Sirocco fan, which is made in Belfast, has not been materially improved by any foreigner though often pirated. It is of quite original design. The ordinary flat propeller fan has blades which, at different points ir length, move at very different velocities: fore drive the air along the air trunk at velocities at different distances from the nd so much energy is lost by friction and Sir Samuel Davidson had an inspiration, and devised a fan which uses a ring, an annulus, of blades only 1/20th of the distal end of the radii, all parts of which ring are sensibly moving at the same velocity. The moving part of the fan is shaped like a tall hat, but instead of the impermeable side, there is a sort of venetian blind arrangement of slats running the length of the hat from the brim to the crown, some 48 of them, and each with a slight uniform twist. The runner rotates in a trunk. Air enters in the centre and the appropriately curved slats, as they rotate, shave off the air near them, slip it through between them at great speed and take more continuously. They pass it through and send it on at a pressure three or four times what any other fan can get, and that is achieved with great economy of energy. Hence it is they are used in men-of-war where the deck openings must be kept as small as possible and yet stokehold pressures must be as high as possible. The Royal Victoria Hospital at Belfast is ventilated with the Sirocco fan, this prophet having some honour in his own country. With reference to Sir Samuel Davidson's honour, a regular correspondent writes to us: "I have two personal recollections of the Davidson fan. When the Royal Sanitary Institute met at Belfast Davidson told me that he had persuaded a man there who managed a tea-shop to have his shop properly ventilated, and that the man afterwards declared that he was very well satisfied, for since he had installed good ventilation his customers ate more cakes. But what is more important, I remember a ward of 40 beds in a ship with bad ventilation, stuffy and hot, and the men could not sleep at night. Two Sirocco fans, three feet each in diameter, were turned loose on it, ventilated and cooled it, and thereafter the men slept. It is a fine hygienic instrument, and has done great good at sea, and it was fitting that the Sailor King should have honoured one who has brought great benefit to seamen."

A STOMACH TUBE FOR INDUCTION OF LABOUR.

None of the various methods of inducing premature labour are free from disadvantages of one or another kind. The use of bougies is safe and certain, but may be very tedious, and the introduction of a hydrostatic bag, such as that of Champetier de Ribes, has the great objection that it displaces the presenting part and often produces a malpresentation, a serious complication when the child is premature. In some clinics rupture of the membranes is practised, and this has the merit of being simple and certain, but renders the labour a dry one, with its attendant risks to the child.

In the June number of the *Dublin Journal of Medical Science* Dr. Gibbon Fitzgibbon describes a method of inducing labour which is perhaps more simple and at the same time more free from danger than any hitherto suggested. On one occasion he found the bougies selected for an induction were spoiled in preparation, and in the emergency he made use of a 30-inch No. 22 stomach tube. He has since used this method in all private cases, and more recently in several hospital cases, and has never found it to fail. The tube must be of soft rubber (No. 20 to 24). The lips of the cervix having been exposed with a speculum and forceps, the end of the tube is passed into the cervix. If after about four inches are introduced the tube sticks, a slight twist on its long axis or a change in the direction of pressure enables it to be pushed right inside the uterus. It coils itself in front of the presenting part in rings about 3 inches in diameter, and when the os is half dilated can easily be removed. Dr. Fitzgibbon states that the tube has the following advantages over bougies: (1) greater ease and certainty of sterilisation; (2) practically complete absence of risk of rupturing the membranes; (3) in the uterus it is confined to the lower uterine segment and so avoids the possibility of disturbing the placenta and also of carrying infection up to the region of the placenta; (4) it is as stimulating as the bougies—in all probability it is more so, as it is all in the lower segment, and exerts a slight elastic pressure from its coiled position. Against these advantages two possible objections occur to us: one is that the tube may not be easy to insert into an undilated cervix, whereas bougies slip in readily; the other is that the coiled tube might displace the presenting part. *However, the method would appear well worth trial.*

At the same time we think that the method of introducing solid bougies, coupled with the digital separation of the membranes round the internal os as far as the finger can reach, if necessary under an anæsthetic, is the safest procedure to adopt.

THE PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION.

The organisation of assistants in pathological and bacteriological laboratories, known as the P.B.L.A.A., was founded some years before the war, but the evolution of its activities was practically at a standstill for five years, and it is only this year that it has been able to bring to a head the educational programme which is the chief object of the Association. During the past week the first examinations for certificates of proficiency in laboratory work have been held, and some 40 candidates have presented themselves in Edinburgh, Liverpool, Manchester, Bristol, and London. Before admission to the examination assistants must have been occupied in laboratory work under specified conditions for a period which varies with the age at which the candidate joined the Association; the examination, which is mostly of a practical character, is conducted by an examining council and examiners who are appointed by the council of the association in coöperation with the committee of the Pathological Society of Great Britain and Ireland. It may be taken, therefore, that the examination will be directed to testing the candidates' proficiency in the lines of work which those in charge of pathological laboratories desire their assistants to pursue. Every laboratory worker knows the value of good assistants in promoting medical education and the advancement of knowledge, and this scheme for raising their standard, for encouraging the boys when they first come to the job by giving them a definite status to aim at, and for arming those who are competent with evidence to that effect, will, we believe, be generally recognised as a substantial piece of progress. The secretary of the Association is Mr. A. Norman, New Haw, Weybridge, Surrey.

THE PARATYMPANIC SENSE-ORGANS.

In the *Arch. ital. di otol., rinol., e laringol.*, Vol. XXXI., 1920, Angelo Ruffini refers to the anatomical investigations of G. Vitali, some of which were published in the *Anatomischer Anzeiger* before the war. One of these discoveries Ruffini regards as of great importance, the existence of a small sense-organ or vesicle situated on the median wall of the tympanic cavity of birds and bats, innervated from the facial nerve. In the pigeon the vesicle has a diameter of 1 mm.; in other birds, for example, sparrows, its diameter is 0·5 mm. Vitali found that after its removal in pigeons the same results obtained as after complete removal of the semicircular canals. He set aside the contention that these results might have been due to injury of the canals when the tympanic membrane was perforated, for histological investigation showed, after removal of the paratympanic organ, degeneration of the vestibulo-cerebellar paths, of the cells of Deiter's nucleus and of the facial nucleus. From the position of this organ under the mucous membrane of the tympanic cavity Vitali concluded that it is an organ which reacts to variations of pressure within the middle ear, the pressure varying with the density of the medium in which the bird finds itself. The bird is thus enabled to determine the density of the medium in which it is flying, and to regulate the innervation of its muscular movements accordingly.

THE COLON AND COLITIS.[1]

[ABRIDGED]

By Lord Dawson of Penn, G.C.V.O., C.B., F.R.C.P. Lond.,
PHYSICIAN-IN-ORDINARY TO H.M. THE KING; PHYSICIAN, LONDON HOSPITAL.

Lord Dawson began the Annual Oration before the Medical Society of London by pointing out that the subject on which he was about to discourse was one that eminently lent itself to debate, so that he regretted that no debate would follow the oration. In an introductory passage he showed how the importance of the colon is manifested by the recurring experiences of daily life, being an organ with highly developed functional activity closely linked up not only with the alimentary tract but with the higher nervous centres. Before drawing the following clinical picture of colitis he pointed out that he was talking only of so-called mucous colitis and not of any condition associated with organic disease of the colon.

The Clinical Picture of Colitis.

The colonic manifestations are abdominal discomfort or pain, disturbance of the function of the colon as shown by irregularity in its evacuation and alteration of its contents, including the expulsion of mucus, and sometimes of blood or sand. By variation in their severity, by the ease with which they are provoked and the frequency of their occurrence, the foregoing features produce varying clinical pictures. Thus pain may be acute or paroxysmal, or dull and aching, or, again, there may be a constant sense of abdominal discomfort and misery. Tenderness may be local, general, or absent. Mucus may be passed in casts, as lumps or in stringy form. In some cases the disease comes on in attacks and at long intervals, and the patient is quite well between whiles; in other instances the intervals of immunity are short and even incomplete, and, it may be, to such an extent that the patient is chronically ill and liable to exacerbations of symptoms on the slightest provocation.

The descending colon will be felt to be tightly contracted, and sometimes in addition the cæcum toneless and distended. Examination by the sigmoidoscope will not usually at this stage disclose signs of inflammation, which shows that inflammation is not a necessary part of the condition; and in some cases where the mucous membrane is red and swollen such appearances may be evanescent and give place to normal appearances after a short interval. Infection does, in some instances, contribute to the picture, just as it is liable to follow disturbances of function in the urinary and biliary tracts. Such infection may be related to tonsils, gums, stomach, or appendix.

The appendix is seldom the focus of infection; more often it shares an infective process on equal terms with the colon; hence the results of its removal for colitis are commonly disappointing. Radiography shows the distal colon to be tonically contracted and irregularly segmented. Side by side with this may be disclosed varying degrees of delay—it may be in the cæcum, colon, in the lower ileum, in the second part of the duodenum. Further there may be displacements of the hollow viscera, such as a prolapsed cæcum and the familiar festooned transverse colon, or again, a movable ascending colon, hairpin bends, and kinks.

With our greater familiarity with X ray appearances in all varieties of cases we know how commonly anatomical irregularities can exist with bowels that function normally. When we recall how coils of intestine kinked and tethered by old adhesions can exist, and acute bends of the bowel be produced experimentally without causing stasis, we are led to conclude that, provided the musculature of the bowel is efficient, these anatomical irregularities need not count for much, especially in those portions of the bowel where the contents are fluid. In specimens examined by Sir Arthur Keith the lumen of the bowel was not encroached upon. and the coils above kinks were not hypertrophied. On the other hand. delay can exist without the presence of any anatomical abnormality. The holding up of the contents of the lower ileum by the ileocolic sphincter is a part of normal digestion. and hypertonicity of that sphincter will produce ileal stasis. In the same way tonic contractions of the descending colon will produce delay in the proximal colon. In short, the immediate cause of stasis lies in the intestinal wall. It is the musculature and its nerve innervation which count, and it is only seldom that anatomical irregularities play an important part.

---

[1] The Annual Oration delivered to the Medical Society of London on May 23rd, 1921.

The orator then pointed out that it was of small benefit to perform ingenious operations to replace or fix viscera unless the anatomical variations produced symptoms calling for relief. He then demonstrated that the colon was not the only part affected, but that cardiospasm, gastric distension, flatulence, symptoms of duodenal ulcer, and affection of the upper alimentary tract may any of them be present, the colitis being one phase of a disturbed digestion in which stomach, duodenum, intestine, and pancreas may all play a part. The well-known features of alimentary toxæmia went far, in the orator's opinion, to give character to any given case of colitis. After commenting on the variability of the extent of this toxæmia and of its association with fibrositis and arthritis he proceeded to discuss the different types of abdominal response.

The Over-responsive Abdomen.

Consider now the patients themselves—observe the difference as to the sex-incidence. Some find females to preponderate largely (Hale-White 85 per cent., Hurst 83 per cent.); others do not (Douglas Wilson 57 per cent.). I rather think the number of males has been increasing in recent years, and, judging by the notes of my cases. I should conclude the percentage of women to be about 70 to 75. The feature which is noticeable with a large number of patients is the over-responsiveness of the abdomen to nerve impressions. They have "barometric abdomens." Fatigue, fear, anxiety, mental stress and strain manifest themselves in their hollow viscera. So do reflex disturbances. Women suffering from the disease often have pelvic disorders which aggravate the intestinal symptoms, and especially during menstruation. Or let these patients have cold extremities (and they often have poor peripheral circulation), especially when they are fatigued. or, again, let them eat when they are cold. and an attack of colitis may easily follow. So much is this the tendency that in dealing with these patients it is part of my routine directions to them never to eat with cold hands and feet, and when they are tired to keep their extremities warm. The effect will sometimes follow the cause with amazing quickness—such quickness as would not give time for any inflammation to develop. I suggest it is rather that reflex nerve disturbance or central nerve disturbance, acting on over-responsive hollow viscera, puts function out of action—certainly motor function, and probably secretory and excretory function also. The rhythm of the intestine becomes disturbed. It is the difference between the regular and the irregular heart, between perhaps normal muscular contraction and auricular fibrillation. Since each zone of the alimentary tract influences the efficiency of the zone below and perhaps above it, if one zone be disturbed the other zones suffer, and thus the orderly sequence of digestion is deranged. Given failure in the function of movement, in the function of secretion (internal and external) and the consequent irregularities of putrefaction and deranged absorption, and "colitis" receives a large measure of explanation.

This over-responsiveness of the abdomen varies in degree. With precautions learned of experience it may, ordinarily, cause little trouble, but should untoward circumstances like over-fatigue, anxiety, bad feeling, occur, the colitis symptom complex may result. But there are some people whose nervous system is cut so fine that the ordinary rough-and-[illegible] life is too much for them, and thus are [illegible]me of those examples of intestinal invalids [illegible]ver well, and in whom chronic ailing is [illegible]d by recurrent phases of acute symptoms. Such patients are not "neurotic." To call them so is a misuse of the term; they may, on the contrary, be heroic, working and even smiling in spite of the load they have to carry. Whether they become neurotic will depend largely on the considerations set forth in the following paragraph.

The Conscious Abdomen.

If a gastro-intestinal tract is constantly causing aches, pains and discomforts, it gets raised in consciousness, with the result that slighter and slighter disturbances and even its very doings produce impressions and discomforts instead of remaining unperceived. We thus get built on the basis of physical disease a superstructure of symptoms and distresses which flourish on themselves and tend to grow apace. There is thus a liability of a *conscious* abdomen being added to a *responsive* abdomen, or in other words, of a *state of mind* being added to a *state of body*.

The degree to which this happens in large measure explains the many varieties and intensities of symptoms occurring in patients who suffer from colitis; and here come in the temperament and character and training of the patient. The buoyant, cheerful temperament with a sense of humour will come off better than the inelastic and sombre temperament. A subject who is introspective and self-centred may be enslaved by the disease, whereas if the subject has the power of sympathetic interest in people and things, can control the mind, and has courage to work, he can, in spite of a colon which is a constant trial, live a tolerably useful life by keeping clear of the worst evils which accrue from the conscious abdomen.

The so-called "neurotic" group consists of those who have developed from their colitis the "conscious abdomen" and have introspective minds. To be neurotic is no essential part of colitis, though it is small wonder that many of the patients become so. It remains, however, a secondary incident, not an essential feature of the disease. How damaging the "conscious abdomen" can become is illustrated by that well-known type of patient who becomes so analytical of the feelings, doings, and contents of his colon as gradually to abandon aught else and live for his lower bowel.

The orator then in a brief digression suggested that the medical profession ought to take up in a large-minded spirit the question of psychical treatment, for the patient with colitis who is in danger of being crushed by his illness is not helped by being dubbed a neurotic. He then referred to the suggestive researches of Sir Arthur Keith into the nervous mechanism of the alimentary tract, and recalled the apt comparison made by the latter between the nervous mechanism of the alimentary tract and that of the heart. He continued:—

We are well acquainted with tachycardia, irregularity of rhythm, fibrillation—heart-block and the responsiveness of heart action to extrinsic impulses. Why should not corresponding irregularities occur in the alimentary tract? And if to disturbed motor function we add the supposition of disturbed secretion and the effect of both of these on the intestinal contents, I suggest the clinical phenomena of colitis receive a considerable measure of explanation.

Stasis, though not a necessary, is quite a common feature of colitis. The two conditions often present one and the same clinical picture, and in their pathological findings there is a close resemblance. They are variants of the same morbid state and the same case may be styled colitis by one observer and intestinal stasis by another.

Alimentary Toxæmia.

Although the term alimentary toxæmia presents to our minds a definite clinical picture the mode of production of the condition is obscure. We may reasonably suppose that a high content of waste products and a damaged intestinal wall are the conditions which favour the passage of toxic products. And these are the conditions which exist in the large intestine in colitis, and sometimes also in the lower ileum. Stasis is not a necessary factor, for in ulcerative conditions of the colon associated with diarrhœa alimentary toxæmia may be a marked feature. Again, strong purgatives, by irritating the intestinal wall, may aggravate rather than allay an existing toxæmia. In colitis there is a retention of contents in the recesses of the colon even when the bowels are open; the latter, in short, do not sweep clean. The degree of toxæmia would depend on the nature of the contents which the colon receives from the ileum, the length of stay of such contents in the colon, and the measure of weakness of the colon defences.[2]

But in cases of colitis and stasis the colon and ileum are not solely responsible for alimentary toxæmia; for the latter will sometimes persist after ileo-sigmoidostomy and colectomy.

The orator here described in detail two cases showing colitis, stasis, and toxæmia in illustration of his statements. He went on to point out that even when the damaged colon has been put out of harm's way and prompt evacuation secured toxæmia may persist. This means that there is a second line of defence, the liver, and that this line may also fail. The colon and liver would thus seem to have a joint responsibility. In some cases the colon defences may have failed so badly that the flood of toxic products is more than even a normal liver can cope with. Given such circumstances, colectomy should succeed. In other instances the liver has a substantial share of responsibility, and then the results of colectomy will be clinically disappointing, even if technically successful.

He referred briefly to the similarity of the symptoms of a "chill on the liver" to those shown after a second injection of a horse serum, and suggest the possibility of an anaphylactic origin of certain attacks of colitis; Dr. A. F. Hurst had pointed out certain suggestive parallels between asthma and colitis. The orator proceeded in conclusion, to discuss the question of treatment.

Treatment.

Owing to the complexity of its origin and the variety of its manifestations, mucous colitis is difficult to treat. The coarse food rich in cellulose advocated by Van Noorden is not a success. It irritates the intestine, and is prone to produce gas. The food should consist of light solids—for example, white fish, first cooked meats, dishes made with eggs, light puddings, &c. Soups should be taken sparingly or avoided. Only a little fluid should be taken with the meals, but sufficient between meals. Fruit and vegetables are a problem; they are often difficult to digest, yet from the point of view of nutrition desirable; mashed potato, cauliflower, and cooked celery and lettuce agree, and of fruits apple is the safest.

In intractable cases the limitation of vegetables and fruit has often to be strict and by some authorities a paste (macaroni) diet is prescribed for a period. The disadvantage of a too-restricted diet is twofold—it discourages the patient, and is apt to result in an insufficiency of essential foodstuffs and vitamins. The latter may be given separately where foods containing them cannot be tolerated in adequate quantity. Sometimes fruit and even raw vegetable like lettuce can be tolerated if taken alone, whereas they remain undigested if mixed with other food. And, generally, colitis patients do better by taking only two main articles of food (courses) at a meal.

It is important for the extremities to be warm, and especially before eating. If the body or mind has been engaged in effort a few moments of repose and relaxation should precede the taking of food. It will often be found that these patients cannot take vigorous exercise of both body and mind on the same day. A business man is often better with only gentle exercise during the week, reserving his physical exertion for the week-end. Where the patient's abdomen is over-responsive the treatment advised should have regard to that fact. Fatigue, stress, and anxiety must be guarded against where possible. Periodic rests, such as a weekly or fortnightly day in bed, helps to secure this end.

A great deal can be done by educating the mind not only to concentrate, but to detach and relax quickly. This is an important aspect of treatment. Physical culture holds an established position. Surely psychical culture is of like importance. The power to rest quickly and relax deliberately is essential to those who feel acutely and work strenuously. Drugs that aid digestion, like taka-diastase and pancreatin, do good. Sleep is apt to be disturbed by distensions of the hollow viscera. Bismuth and sodium bicarbonate with carminative, and if necessary a few minims of nepenthe, given at bedtime, will help this condition. Aperients should be gentle, and for clearing the bowel castor oil is the best. Very often little aperient is needed if paraffin is taken regularly, though there are patients in whom paraffin is ejected alone and even incontinently. Special care in the use of aperients is needed when bacilluria exists. An essential indication is to secure the emptying and cleanness of the colon. This is secured by intestinal lavage. Bismuth in bulk (℥ ij.) administered in bread and milk or jelly taken every week or ten days is often of benefit. It seems to act by scouring the colon. Where there is much fermentation an ounce of wood charcoal may be mixed with the bismuth. Intestinal antiseptics are disappointing.

Where the above measures fail to secure evacuation and cleansing of the intestine appendicostomy is a sound and safe procedure, and is often productive of considerable benefit.

Colectomy.

Sufficient experience has now been gained to pass the operation of colectomy under review. The results as a whole have not been encouraging. Apart from its magnitude and therefore risk, the operation seldom restores to a patient anything approaching a normal life. Patients will express doubts as to whether they have gained enough to have made the operation worth while.

As the cases quoted above show, technical and clinical success do not always go together. Further, there are not a few instances where the operation completely fails in its objects and leaves the patient as wrecked if not more wrecked in health than before. Now and again the results are excellent and succeed where previous measures have failed. I have under observation a case in which a transformation was effected by colectomy, and now, after ten years, the patient continues in good health.

The indications for colectomy would seem to be: 1. Where the motility of the colon is so spent that all other measures fail to prevent stasis within it. 2. Where the colon is so damaged in its defences that, in spite of every effort to keep it cleansed, toxic products get through in such abundance as to ruin the health of the patient. But here, too, there is risk that the second line of defence in the liver may be damaged also.

Hemicolectomy.

Hemicolectomy is on a different footing. The operative risk is small, and if it fails in its object there is little risk of the patient's condition being worsened. If the failure of function is in the proximal colon the prospect of success should be good, especially if the ileo-colic valve is preserved in the implanted portion, as has recently been done. Unfortunately, however, there is sometimes too much mischief in the distal colon for the operation to be adequate. When such is the case and a complete colectomy appears to be inevitable, I suggest that it is worth while considering in each case whether colotomy would not be efficient and preferable. The thought of colotomy is, no doubt, in discord with a fine surgical sense, and its performance carries a feeling of disappointment to the surgeon that circumstances do not permit him to do something better. But in relation to this particular problem it has advantages. It is a simple operation, patients achieve a considerable accommodation to its inconveniences, and, if it fails, further surgical procedures are not precluded.

---

[2] Graham Brown has described an amine (p-hydroxy-phenylethylamine) which is formed in the intestine under conditions of stasis by the putrefactive destruction of proteins through the action of anaerobic bacteria. This toxin is converted in the liver into p-hydroxy-phenylacetic acid, and as such can be found in the urine in cases of alimentary toxæmia. It acts on the sympathetic producing hypertonus.

On the other hand, complete colectomy is the last and irretrievable word; it offers but a modest prospect of success, and its failures, not a few in number, are sometimes apt to be such dire failures as to mean for the patients misery and suffering little capable of alleviation.

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Staffordshire County Council.

IN his annual report for 1919 Dr. George Reid has omitted the summary of the district reports which he was in the habit of making before the war because of the high cost of printing and because the County Council could hardly take action, involving expenditure, at the present time. He states, however, that the reports give considerable prominence to the question of housing. The county health visiting scheme makes good progress. Previous to 1919 two centres for infant welfare and school medical work had been established under the joint scheme of the County Council and County Education Committee. Since that date ten new centres have been established. During the year an Infant Welfare Travelling Exhibition has been purchased and has toured through the county with good results. Twenty-one women have been sent for training as midwives, five subsidies have been granted to practising midwives, and six new local nursing associations have been formed; an income scale has been fixed governing the recovery of fees paid to doctors called in by midwives. It has been necessary to be content with a lower standard for sewage effluents, owing to the deterioration of some of the sewage disposal works during the war. Of the two venereal disease centres already established, the centre at the Wolverhampton General Hospital has been a great success, but the North Staffordshire Infirmary Centre may have to be discontinued owing to the small attendance. Two subsidiary centres have been begun at Tamworth and Lichfield, and there have been negotiations for others at Leek and Walsall, and in connexion with the hospitals at Stafford and Stourbridge. The medical practitioners have coöperated in the scheme and about 20 of them have qualified themselves for the administration of salvarsan or its substitutes. The number of Staffordshire cases of venereal disease treated during the year is given as 666, and the estimated population of the administrative county (for death-rate) as 674,671. The number of midwives practising in the county was 284, of whom 57 were over the age of 65. The mean number of cases attended per midwife in the three divisions of the county was as follows: North, 27·4; Central, 23·3; South, 65·2. Midwives attended 70 per cent. of the births in 1919 and 66 per cent. in 1918. Medical help was sent for by midwives in 1809 cases, as compared with 1165 in the previous year, and Dr. Reid attributes the extraordinary increase to the fact that the County Council now pay the fees of the doctors called in. The figures show that the midwives sent for medical help in more than 17 per cent. of their cases.

The number of cases of ophthalmia neonatorum reported was 85, 60 slight and 25 severe. Of the 25 severe cases 18 recovered without injury to sight, 5 died from other causes, and 2 suffered slight damage to sight. A clear history of venereal disease was established in 38 cases. The loss of sight among the survivors of the severe cases reported during the last three years (who numbered 72) amounted to one eye in one case and both eyes in another. Of the 284 ising midwives, 275 are able to read a thermo- 261 are able to read and write, and 189 are pass a catheter.

The birth-rate was 21·5, to be compared with 24 for the previous quinquennium; the death-rate was 14·0 compared with 15·0. The infant mortality rate in the urban districts was 96 and in the rural districts 72, compared with 103 and 83 respectively during the previous year. There was a great reduction, as elsewhere in the country, in the number of notifications of tuberculosis. Dr. Reid explains this by the swelling of the numbers in the early years of notification by the inclusion of old-standing cases. There was, however, a great reduction throughout the country, both in deaths and notifications from tuberculosis of the lungs in 1919, compared with the war years, and it is possible that this reduction was largely due to the cessation of war industrial work, taken up or continued from patriotic reasons by persons of both sexes who were unfit to stand the strain.

County of Dumfries.

The annual report for 1919 shows that the population of the county for 1919 was 46,458. The birth-rate was 21·7. Of the 1009 births, 120 were illegitimate. The death-rate for the county was 13·06 and the infant mortality rate 89·2. Dr. J. M. Ross records an outbreak of mild scarlet fever in the parish of Sanquhar and thinks its spread may have been helped by the picture house, which was extremely popular and crowded at every performance during the outbreak. There was no special prevalence of diphtheria compared with previous years, 75 cases being notified with three deaths. As in other districts, a decrease is recorded in the notifications of tuberculosis. Dr. J. Ritchie, the tuberculosis officer, says: "The sharp rise in the number of notifications of tuberculosis in 1916 and its subsequent decline is of interest. It may probably be connected with the influx of war-workers from other parts of the country, which took place about that time." The county sent 11 patients to the Westmorland Sanatorium, 4 to the Bridge of Weir Sanatorium, and 12 and 19 respectively to Lochmaben Hospital and Dumfries and Galloway Royal Infirmary. It would seem from the report that a sparsely populated county like Dumfries is an ideal district for the extensive use of shelters, and the following remarks by Dr. Ritchie on this subject are of interest (p. 27):—

> "I am inclined to believe that of all measures at present available throughout the county for anti-tuberculosis work the provision of shelters is, perhaps, the most important. Provided that the patients are not too far advanced when commencing shelter treatment, and that they are sufficiently intelligent and conscientious to carry it out properly, excellent results may be obtained. Many patients, conscious of the benefit they have experienced, become enthusiastic devotees of shelter life, and one is not infrequently faced by the dilemma of having either to take away a shelter from a patient who is anxious to continue 'shelter life,' or to leave unprovided one who is anxious to begin it. There are at present four patients in the county who were provided with shelters during 1914 and have used them constantly since. All had well-marked pulmonary tuberculosis and were excreting tubercle bacilli when they were introduced to 'shelter life'; and although one might hesitate to say definitely that they have been cured, in three cases the disease has been arrested and the patients are fit for full work, while in the fourth there has been great and progressive improvement and the patient has been doing light work for several years. That equally good results could have been obtained by treating those patients without shelters is very questionable; and to compel them against their strongly expressed wish to return to the relatively unhygienic conditions of cottage life—with the possibility of causing a recrudescence of the disease—in order that their shelters may be used by other patients, is a responsibility that one is rather chary of assuming."

The report includes a housing survey of the five districts into which the county is divided, and also schemes and estimates for the extension of the Rockhall waterworks. As elsewhere, the sewage disposal works have deteriorated owing to the war from lack of attention. Under the heading "Dairies," Dr. Ross says:—

> "Efforts are being made to improve the quality by the institution of a system of 'graded' milk, under which a higher price may be charged if a certain percentage of marks for condition of premises, cows, milkers, &c., is obtained.

The idea is good so far, but behind it lurks the danger that the less wealthy consumers may have to be content with milk of a poorer quality."

The report concludes with particulars of sanitary conditions in the five small boroughs in the county: Annan, Sanquhar, Lockerbie, Moffat, and Langholm. The burgh of Annan has had an extraordinary experience in overcrowding. The population in 1914 was 3851 and in 1917–18 rose to 5517. Since the Armistice the population has gone down to 4205 in 1919.

Stafford.

The annual report for 1920 shows that the estimated population is 27,762, and the birth-rate was 22·4, as compared with 17·9 in the previous year. The death-rate was 10·66 and the infant mortality rate, 65·9, was the lowest ever recorded. The death-rate from pulmonary tuberculosis is rather high, 1·08 for 1918 and 1·26 for the decennium 1910–1919, and Dr. C. Banks points out that this disease is "somewhat prevalent" among the boot and shoe operatives. Dr. Banks condemns the use of wooden tubs as receptacles for house refuse. He also thinks that "more might be attempted in the way of preventing the access of impurities to the milk during the course of milking and distribution," and that "there is much unnecessary exposure of food-stuffs such as bread, pastry, sweets, and other articles, permitting pollution by dust and flies." There is an active infant welfare centre, and it is mentioned that "in Stafford very many girls are employed in the factories up to marriage, so that they have little opportunity of getting to know anything about the management of children." Six cases of ophthalmia neonatorum were notified during the year and all were cured without permanent blemish. Stafford has its housing question: under the council's scheme for erecting 440 houses on two estates, 32 houses were completed and occupied by Dec. 31st, 1920. There are at the present time 91 houses in the borough which are unfit for habitation, but they cannot be demolished until facilities exist for rehousing the occupants.

Leicester.

The annual health report for 1920 states that the estimated population for 1920 was 245,465. The general death-rate was 11·7 per 1000, the lowest ever recorded. The infant mortality rate was 89·4 per 1000 births, again the lowest on record. Only once before has the infant mortality been under 100—viz., in 1919, when it was 98. The mortality rate among illegitimate infants was 145. The tuberculosis death-rate is also lower than ever. The rise in the death-rate from pulmonary tuberculosis which occurred during the war has now disappeared, in spite of the over-crowding, and acute shortage of houses. The birth-rate showed a remarkable increase—viz., to 21·0 from 15·3 in the previous year, and the marriage-rate was also very high. To quote from the report:—

> "The two principal industries of Leicester are hosiery and footwear, but there are many other important trades—e.g., engineering, tailoring, cardboard-box making, elastic-web manufacture, printing, &c. With the exception of the boot and shoe trade, which is recognised as being a bad trade for tuberculosis, none of these industries can be regarded as being inimical to health."

A large amount of female labour is employed.

> "At the last Census, in 1911, 47 per cent. of women were returned as being engaged in occupations other than in the home."

One of the events of the year was the opening of the new municipal maternity home with accommodation for 26 patients. The number of confinements in
[illegible] new home during the first quarter of 1921 was 99.
[illegible]ter is well provided with the amenities of a
[illegible] city, and the amount of ground used for allot-
[illegible] said to be much above the average, a fact to
[illegible] C. K. Millard attaches great importance. In
[illegible] on the high marriage-rate, Dr. Millard
[illegible] the impossibility of getting houses may
[illegible] seeing that young
[illegible] he parents, and are thereby
[illegible] utlay of starting housekeeping. He considers that the increase in the birth-rate adds to the seriousness of the housing shortage, the increase of the population in 1920 being 3060.

The soft water from the Derwent was found to act on hot water pipes and lime has now been added to prevent this. The pail-closets have been converted into water-closets, but there are many houses which only have a share in a water-closet. Much difficulty arises over defective dustbins, and Dr. Millard suggests that the corporation should replace them when necessary. "As almost every ratepayer uses a dustbin, nearly all would stand to benefit by the arrangement." Although there is a municipal abattoir, there are still 55 registered slaughter-houses which "should be got rid of as soon as possible."

Dr. Millard estimates that 90 per cent. of the native-born population of Leicester under the age of 36 are unvaccinated. There were three deaths from enteric fever during the year. Of 101 notified cases of ophthalmia neonatorum, in only one case did permanent blindness or serious injury to sight result. The notified cases of pulmonary tuberculosis as well as the deaths showed a marked decrease. There has been a slight decrease in the number of new cases presenting themselves for treatment at the special (V.D.) clinic at the Royal Infirmary. At St. Mary's Home 12 beds are reserved for unmarried girls suffering from V.D. who are without proper lodging or accommodation. These cases remain under treatment at the expense of the corporation so long as they are considered in an infectious condition. Such provision is undoubtedly of great value. Some difficulty is experienced in getting pregnant women suffering from syphilis to accept treatment. The babies of ten such women treated in 1919 were all born healthy, and the nine still surviving are believed to be still healthy.

Very successful lectures on sex hygiene have been given to the boys and girls leaving the secondary schools. The lecture to boys was given by Dr. Vincent Shaw, and that to girls by Prof. Winifred Cullis, D.Sc. Dr. Millard has much to say about the housing shortage and the "exasperatingly slow" provision of new houses. The scheme of the sanitary committee for bringing the older houses up to date was stopped by the war, and it has not been possible to resume it owing to the financial position of the owners. According to Dr. Millard great difficulty is experienced in getting even ordinary and necessary repairs carried out. Some of the defects in the older houses mentioned by Dr. Millard are: The want of a separate water-closet; a common tap in the yard for the supply of water; the absence of a sink with waste-pipe; the absence of a copper, or facilities for washing clothes; kitchen ranges with no boiler or an inefficient oven; no provision for food storage, &c. There is a very active maternity and child welfare campaign in Leicester, supported by voluntary workers. The antenatal clinic is now well patronised. Hospital treatment is provided for sick infants at the isolation hospital (15 cots). There are now two maternity homes to meet the need aggravated by the house shortage.

As regards tuberculosis, the report states that the medical men of the city, as well as the general public, now fully realise the value of the dispensary as a centre for diagnosis. Twelve shelters are available for loan to patients for use on their own ground, free of charge. More time has been available for the examination of contacts during the past 12 months, though not nearly so much as was desired.

HEALTH OF THE BELGIAN CONGO: A CONFERENCE.—Dr. A. J. Orenstein, chief of the Rand Mines Department of Sanitation and formerly chief assistant to the late Surgeon-General Gorgas during his sanitary work in the Panama Canal, has left Johannesburg, South Africa, on a visit to the Belgian Congo, in order to confer with the Belgian authorities on schemes to improve the health of the Congo. It is hoped that with the drainage of certain tracts the incidence of malaria will be greatly diminished, and that in other ways the general health conditions of the district may be improved.

Correspondence.

"Audi alteram partem."

THE ARM-TRAINING SCHOOL AT ROEHAMPTON.

To the Editor of THE LANCET.

SIR,—The account of the Arm-Training School at Roehampton which Dr. C. Jennings Marshall contributed to your issue of June 25th cannot but be gratifying to the surgeons who have been working at Queen Mary's Convalescent Auxiliary Hospitals for the last six years and to Captain Rowlatt Maxwell, late C.F. Chief Arm Instructor to the Ministry of Pensions.

But while congratulating Dr. Marshall on the accuracy with which he has reproduced the result of the experiences which Captain Maxwell communicated to him, I cannot but regret very deeply that he has omitted to acknowledge the source of his information. First at Charterhouse Military Hospital and since at Roehampton and all over the United Kingdom Captain Maxwell has done invaluable work in educating amputees to make a good use of their arms, and he should receive every credit for his efforts and achievements.

I am, Sir, yours faithfully,

E. MUIRHEAD LITTLE,

Visiting Surgeon to Roehampton Hospital under the Ministry of Pensions.

Seymour-street, Marble Arch, W., June 29th, 1921.

*** We regret that in the same issue of THE LANCET as Dr. Marshall's account of the Arm-Training School at Roehampton we did not remind our readers of the circumstances in which the hospital came into being. They were noted at the time, but might well have been repeated. The hospital was first started in 1915, with Mr. E. Muirhead Little, Mr. T. H. Openshaw, Mr. A. S. B. Bankart, Mr. R. C. Elmslie, and Mr. E. M. Corner as the honorary surgeons in charge of the actual work of the hospital. Early in 1916 the committee of the hospital decided to appoint one orthopædic surgeon in supreme charge, and Mr. Little was asked by his colleagues to accept the post. He held this post with results which must be extremely gratifying to himself and to his orthopædic colleagues until the control of the surgical work of the hospital was taken over by the Ministry of Pensions in April, 1920. Since this time Mr. Little, Mr. Openshaw, and Mr. R. H. Campbell have been visiting surgeons until the present moment, when Mr. Little remains in single responsibility. There are three resident surgeons, and if this seems a large staff, it must be remembered that there are not only 200 in-patients whose needs have to be met, but a very large number of out-patients, while as many as 600 artificial limbs are turned out every month, and a vast mass of repair work is discharged. Captain Rowlatt Maxwell, the officer who is depicted using the artificial arms in the illustrations to Dr. Marshall's paper, initiated arm-training in this country. His practical work, first at the Charterhouse Military Hospital and since at Roehampton and many other centres in the United Kingdom, has been of the first importance to orthopædics. We regret that we did not append to Dr. Marshall's article a résumé of the history of the hospital.—ED. L.

"PSYCHOTHERAPY."

To the Editor of THE LANCET.

SIR,—The practical meaning of the title at the head of the following remarks may fairly be taken as "treatment of mental disorder." "Therapy" implies disorder, and the qualifying word "psycho." on the analogy of the old-established term "psychology," does not imply any preconceived theory as to the genesis of what we call mind, or even suggest any particular definition of the term "mind." But in recent years and with rapidly increasing frequency, both in medical and daily-journalistic literature, we find the term "psychotherapy" applied to the treatment now known as "psycho-analysis," of which the basis is Freud's doctrine of the "Unconscious Mind." The article by Dr. S. Herbert in your issue of June 11th gives me the impression that the author greatly underrates the importance that is attributed by English alienists and neurologists to the sex-factor in the genesis of mental and nervous disorders. He says, for instance, that "there still exists among English psychotherapists" (here duly using the word in its proper meaning) "a good deal of reluctance to recognise to the full the importance of the sex-factor as a cause of psychoneuroses"; and, further, that "those who *try to minimise* the sex-factor should not *forget* that man is polyerotic"! The only other quotation I need make from Dr. Herbert's letter is as follows, "It is the recognition of the sex-factor which enables *us* to deal with such neuroses in a *satisfactory* manner, and effect a *proper* cure by means of *psycho-analysis*" (italics mine).

I think that it may be fairly inferred from the passages quoted that Dr. Herbert, who, in writing thus to THE LANCET, is addressing psychotherapeutists who do not accept the larger part of Freud's teaching, is both identifying "psycho-analysis" with "proper treatment," and is ignoring the fact that at least the majority of English medico-psychologists, in studying any case of mental disorder, are not only well aware of the importance of the sex-element, but also make practical use of that knowledge both in diagnosis and treatment. Nor is this knowledge and practice by any means confined to specialists in medico-psychology; it is widespread among the general body of practitioners. Again, the undoubted fact of the "polyeroticism" of the human being is not denied by anyone who would not deny that humans are animals. Any student of even the earliest psychological works of the great philosopher and alienist, Henry Maudsley, so recently lost to us, must recognise that the importance of the sex-factor in the genesis of mental disturbances, at the least, was emphasised by accredited teachers long before this doctrine was exaggerated, transformed, and linked up by Prof. Freud and others with what most scientific thinkers deem to be a false psychology.

I have no intention to enter here into fuller criticism of the Freudian teaching or of the growing tendency, which is affecting the public at large, to identify not only "psychotherapy" but "psychology" itself with "psycho-analysis"; nor can I dilate on what I know to be the evil and dangerous effects of the practice of "psycho-analysis" in some hands and in certain cases. Such cases are, of course, not published. Nor could they be published in any detail, even for the patient's sake alone, who might readily be identified in even anonymous reports.

But this much may be said about polyeroticism, its relation to psychotherapy, the causal part it plays in mental disorder, and the increasing attribution (now made by many) of the psychoneuroses to repressed eroticism, whether "poly" or "mono." There is no doubt that in certain periods and certain circumstances the prevailing repression of the sex-impulses leads to the establishment of some form of neuropathy or psychopathy. But a great measure of this "repression" is the rule of custom in nearly all civilised countries. It is, indeed, one of the essential and first elements of human civilisation. Yet neuropaths and psychopaths are still far from dominating any civilisation by their numbers. What *may* happen, at least for a while, if the practice of psycho-analysis should spread still further among us, is a question of grave import.

One last reflection, aroused afresh by the deeply interesting and weighty Croonian lectures on the "Objective Study of the Neuroses," delivered in June last by Dr. F. L. Golla at the Royal College of Physicians of London. The whole trend of the popular hypothesis underlying the Freudian doctrine and treatment tends to distract attention from the methods of experimental psychology in studying the normal and morbid workings of the brain and the rest of the nervous system. By such methods alone—not by assumptions and guessing—can an approximately true science and practice of medico-psychology be attained.

I am, Sir, yours faithfully,

July 2nd, 1921. H. BRYAN DONKIN.

THE ACTION OF TARTAR EMETIC IN BILHARZIASIS.

To the Editor of THE LANCET.

SIR,—In papers and annotations dealing with the cure of bilharzia with tartar emetic the point has been mentioned as to whether the worms or the eggs are first affected by this drug. For several years before the discovery of the tartar emetic cure I had been experimenting with various methods, and I had found one which in my hands gave very encouraging results. The starting point of this treatment was that I had observed that the urine of bilharzial patients, who from any cause had to be in bed on a fluid diet, improved considerably, but that soon after they received full diet again the previous condition was restored. I regarded this diminution of the external evidence of the bilharzial infection as due to the fact that, owing to the reduction in the quality of the portal blood, the worms were producing eggs in greatly reduced quantity. There can have been no question of any direct effect on the eggs from such treatment. The decrease was noticeable after about a week of treatment. I received confirmation, or what I looked on as confirmation, of this view from the fairly numerous cases of Egyptian fellaheens, who, being accustomed to live very frugally at home, complained, shortly after their arrival in the Sudan, where they were comparatively richly fed, that their urinary trouble, which before had been slight or unnoticed, had become tiresome and severe. In the course of my experiments I was able to reduce or increase the number of eggs passed practically at will.

My view which developed from these observations was that the usual time for a crop of eggs to take from the worm to the urine was five to seven days by the normal routes, but, of course, many eggs missed their way and took much longer to arrive. As the improvement in cases of bilharziasis takes place in much about the same time, I have always considered that the first effect of tartar emetic was to limit the production of eggs. In the article by Archibald and Innes in the *Journal of Tropical Medicine*, April 1st, 1919, on a so-called fatal result from tartar emetic treatment of bilharziasis in an Egyptian soldier who died of influenza, bilharzial eggs were found in the tissues but no worms could be discovered. Further, I find that the eggs in cases of *Bilharzia Mansoni* take a longer time than in vesical bilharziasis to become brown and granular, and this points again to the worms and not the eggs being primarily affected.

I am, Sir, yours faithfully,
V. S. HODSON,
Director, Khartoum Civil Hospital.
Khartoum, June 16th, 1921.

“CIRCULAR 202.”

To the Editor of THE LANCET.

SIR,—Circular 202 on the Prevention and Treatment of Venereal Diseases, recently issued by the Ministry of Health, must, on the whole, be welcomed by those who believe that instruction in the methods of self-disinfection is a necessary health measure for the prevention of venereal disease. True, the circular states that the Government, because of the moral and social considerations involved, cannot give its “official support” to self-disinfection, yet, although self-disinfection in exact terms is disavowed, the principle of self-disinfection is strongly supported. This is seen in a later paragraph, where the Minister advises the issue of leaflets warning the public that it is the *duty* of all individuals who have incurred the risk of contracting disease *to cleanse themselves immediately and thoroughly, and thereby diminish the risk.* “Cleansing immediately and thoroughly,” presumably with soap and water, is nothing else but a form of self-disinfection; the use of soap and water is neither so effective nor in many cases so readily available as is the employment of a portable disinfectant such as permanganate of potash, but the principle in the two cases is identical. The circular is therefore a distinct advance on past pronouncements of the Ministry on the subject.

But there is an even greater concession. Later on in the circular it is stated that the Minister considers it desirable to state that he is advised that a chemist does not commit an offence against any Act of Parliament by selling substances “capable of being used as disinfectants against venereal diseases.” The clear inference to be drawn from this statement is that although the Government can give no official support to self-disinfection, yet the Minister is so alive to its value that he goes out of his way to add a paragraph directly encouraging the practice.

Although some of us may regret that the support given to self-disinfection is not so whole-hearted as we could have wished, yet allowance must be made for a Government which is attempting to deal with a subject upon which many people hold strong convictions. Experience has taught me to recognise that the advocacy of a policy of self-disinfection, on first consideration, always arouses strong opposition in certain quarters because of the conviction that it may prove an incentive to immorality, but I believe that if only the whole facts of the case are clearly and calmly discussed the opposition is to a great extent disarmed. I have formed this opinion as a result of the course of events in Portsmouth, and I am further strengthened in this opinion by the fact that the Special Committee of the National Birth-rate Commission, a body composed under the chairmanship of the Bishop of Birmingham of individuals whose names alone are a sufficient guarantee that no practice which tended to encourage vice would ever receive the slightest recognition, have reported strongly in favour of a policy of instructing the public in the methods of self-disinfection.

I regard Circular 202 as a step in the right direction, and I feel confident that it will not be long before a still further advance is made towards the policy so strongly advocated by the medical profession as being the best practical means for controlling the most serious menace at the present time to the health of the nation.

I am, Sir, yours faithfully,
A. MEARNS FRASER,
June 28th, 1921. Medical Officer of Health, Portsmouth.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of THE LANCET.

SIR,—Dr. W. J. Grant, in THE LANCET of June 25th, still entertains misgivings in regard to many errors in physics which I am supposed to have committed. Let us define the issue. One of the facts I attempted to establish in my paper is that under the influence of digitalis we often get a decline in the systolic and diastolic pressure at the very moment when the output of the heart per single contraction is increased. I maintain that it is a physical possibility to obtain an increased volume of flow per unit of time through the circulation *under these conditions.* My reasons for such an assumption are as follows:—

1. During the systole the velocity of the blood in any part of the arterial circulation is about three to four times greater than during the diastole. It follows from this that if the systolic output is increased a greater amount of fluid in the arterial system circulates at a greater speed than under normal conditions. In these circumstances the total volume of blood leaving the arterial system in a given time might be greater than normal. On this supposition the arteries would contain less blood during the diastole than normally. But as the systolic pressure is made up, (other conditions remaining the same), of the volume of blood contained in the arteries during the diastole plus systolic output, it follows that this pressure might become lower than normal, although the single

systolic output is greater than before. I say, therefore, that provided the force of the heart is increased at each systole, one might get an increased flow of volume through the arterial circulation without a rise in the systolic pressure.

2. It is a fact that the lower (owing to increased cardiac output) the pressure in the veins near the heart, everything being equal, the greater the difference in pressure between the capillaries and the veins near the heart. I say that under these conditions it is possible to get an accelerated flow of blood through the veins per unit of time without a rise in the pressure of these vessels. (Dr. Grant says it is impossible to get an increase of flow through the veins without an increase of pressure on the venous side of circulation. He will be surprised to learn that, as a matter of fact, in cases where there is an increase of pressure in the veins, as in heart failure, the velocity of blood in these vessels is diminished.)

Dr. Grant may consider these facts an infringement of the elementary laws of physics, but they happen to be elementary principles of physiology. The issue is simple. Dr. Grant asks in his first letter "How it is possible to obtain an increased flow of volume per unit of time through the arterial system without either dilatation of the capillaries or rise of the blood pressure," and being quite sure that such a thing is a physical impossibility, he thinks that the conclusions arrived at in my paper are "improbable." I on the other hand say that if he had been acquainted with the elements of physiology he would have been unable to discover any of the numerous errors in physics which he thinks I am guilty of. It is for readers of THE LANCET to judge between us, and I am sure they will not be misled by empty phrases such as "physical laws."

I will not discuss the question raised by Dr. Grant in his second letter in regard to systolic pressure and output. He accepted my proposition in his first letter, and the discussion cannot be diverted from the original issue. All I will say is that his arguments in his second letter are as powerful as those in his first.

I am, Sir, yours faithfully,

Liverpool, June 25th, 1921. I. HARRIS.

ON DEATH FROM RESPIRATORY AND NOT FROM CARDIAC FAILURE.

To the Editor of THE LANCET.

SIR,—It has fallen to my lot on four occasions when operating for cerebellar abscess to have witnessed sudden and complete cessation of respiration, apparently from paralysis of the respiratory centre. In each of the four cases there was no interference with the cardiac centre, the pulse-rate being quite unaffected. In each case artificial respiration was kept up while the abscess was opened and drained with all possible speed. So soon as the undue intracranial pressure was relieved by the evacuation of the contents of the abscess cavity normal respiration was restored, thus confirming Sir Dyce Duckworth's dictum, "That the respiratory centre is clearly more sensitive than its neighbour the cardiac centre, and is the first to yield under undue intracranial pressure." These four cases are referred to in "Diseases of the Ear" (Milligan and Wingrave).

I believe that excessive intracranial pressure so constricts the lumen of the smaller blood-vessels of the brain that such a state of anæmia supervenes as to prevent the working of the various higher nerve centres, the most sensitive—viz., the respiratory—giving out first of all.

I am, Sir, yours faithfully,

Manchester, July 4th, 1921. WILLIAM MILLIGAN.

UNIVERSITY OF SHEFFIELD.—The following candidates have been successful in the Final Examination for the degree of M.B., Ch.B.:—May T. Bassett, Edgar S. Clayton, Ronald D. S. Baron, Richard T. Lee, Elsa F. Page, and Robert Platt.

Obituary.

H. WORK DODD, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE ROYAL FREE HOSPITAL.

MR. H. Work Dodd, who died at his residence in Harley-street on June 28th in his sixty-second year, was born at Victoria, Vancouver Island, and was the son of the late Mr. Charles Dodd, of the Hudson Bay Company. He was educated at Norwich Grammar School, and entered at St. Bartholomew's Hospital, where his kindly disposition and genial personality made him many friends. Qualifying with the membership of the Royal College of Surgeons of England in 1881 he obtained the L.S.A. in the following year, and shortly afterwards became a licentiate of the Royal College of Physicians of London. He became a Fellow of the Royal College of Surgeons in 1888. As a young man he was for some time surgeon to a cable-laying telegraph ship, which gave him the opportunity of visiting many parts of the world and gathering useful experience. He thus acquired a taste for travel, and on many subsequent occasions spent his holidays in Norway and other parts of Europe.

He became a resident medical officer at the Royal Free Hospital, and in 1890 he was appointed ophthalmic surgeon and clinical lecturer on ophthalmic medicine and surgery in that institution, succeeding the late Mr. Grosvenor Mackinlay. This post he held until a few years ago, when he was appointed consulting surgeon. He was also consulting surgeon to the Royal Westminster Ophthalmic Hospital, and consulting ophthalmic surgeon to the West London Hospital for Nervous Diseases. He was a good operator and took a keen interest in his work. He was, perhaps, especially interested in the more uncommon diseases of the eye, and among the papers he wrote were those on Green Vision and Orientalism. He was a fairly regular attendant at the meetings of the Ophthalmological Society. At the Royal Free Hospital he was much liked both by his colleagues and by the students.

He leaves a widow, a daughter, and two sons, both of whom are doing well in the Indian Civil Service and in the Diplomatic Service respectively, and have evidently inherited much of their father's ability. His loss will be deeply regretted by a wide circle of personal friends. J. B.

DOUGLAS VERNON COW, M.D., B.C. CAMB., D.P.H.

Dr. Douglas Vernon Cow, of the Pharmacological Laboratory at Cambridge, who died on June 23rd, at Redruth, Cornwall, where he had gone for his health, was born in London in 1880 and was therefore only 41 years of age. He was educated at Harrow, and Trinity College, Cambridge, taking honours in the Natural Science Tripos in 1902.

After studying medicine at St. Thomas's Hospital he proceeded in 1905 to the M.B., B.C. degrees, and for the following two or three years took up general practice at Warwick, but in consequence of ill-health resigned and went for a voyage round the world. He returned to Cambridge in 1910 in which year he proceeded to the M.D. degree, and after working in the Pharmacological Laboratory obtained a Beit Research Fellowship. As a result of work in Vienna he published in the following year a paper on Diuresis. Later he became Assistant to the Downing Professor of Medicine and Examiner in Pharmacology at Cambridge.

Dr. Cow, who had been lecturer on pharmacology both at King's College, London, and at the Middlesex Hospital, wrote much on that and collateral subjects for scientific journals and for the proceedings of medical societies, and in 1920 published in the Students' Synopsis Series a volume on pharmacology. He leaves a widow, daughter of the late Mr. John Douglas Browne, of Belfast, but no children.

THE PRIVATE CLINIC SYSTEM.

ADJOURNED DEBATE.[1]

AT a general meeting of Fellows of the Royal Society of Medicine, held on July 4th, with the President, Sir JOHN BLAND-SUTTON in the chair, the adjourned debate on private clinic systems in this country took place.

Dr. A. LAPTHORN SMITH said he had often felt the truth of Sir William Osler's remark that it was a pity that the poor rich could not get as good hospital treatment as the very poor. Years ago, during a stay in Vienna, he had visited a large private hospital there, entirely occupied by paying patients who were graded in four classes, from noblemen to poor tradesmen. In the early morning more than 50 doctors attended, and as each one entered he registered his name on the notice board and marked it off as he left. A busy doctor sometimes made from 10 to 20 visits in that one building, for every one of which he was paid; consultation was speedily secured by a note to another doctor. Best of all, as he went out each doctor handed his list of patients to one of the bookkeepers, who at once charged up the visit on each patient's bill, so that before the patient left the hospital a cheque was handed to the doctor without the mention of money to the patient.

There is no reason, continued Dr. Lapthorn Smith, why such an institution could not be built in the neighbourhood of Regent's Park, or a little further out, provided the cost of a highly ornamental building, and the supposition that a large amount of capital was necessary, could be avoided. The building at Rochester, U.S.A., was plain wood, with a passage way up the centre, about 12 rooms on each side, and a large waiting-room opposite the front door, through which came several million dollars per year. At the Mayo Clinic the doctors had never to speak of money; the cashier finds out the amount of the patient's monthly income, and charges approximately that amount for professional services. He had just had a letter from a friend on the Mayo staff, saying: "Since you were here the Clinic has extended to such an enormous institution you would not recognise it at all. About 350 beds in each hospital." It had been doubted whether patients paid the heavy fees willingly; he had himself spoken to many who had paid large sums at the three private clinics, and they had had nothing but praise for the splendid examination.

The second private hospital of the group, at Battle Creek, Michigan, began with one doctor; in a few years he had a hundred-bed brick building, and employed assistants at fixed salaries; then he trained his own assistants, and now has a new hospital in addition to the old one. The patient picks a doctor, who states his case and the opinions which other doctors have given at different times; the youngest man gives his views first, and so on until it is the turn of the chief. The consultation may be adjourned for a special examination; the different reports are read next day and the best treatment decided on. At Baltimore the patients see the chief first at his consulting room, and are then sent to a nursing home. During the week five or ten specialists call on them there and make thorough reports to the chief.

Dr. C. O. HAWTHORNE pointed out that the terms private clinic, group medicine, and team-work had during the previous discussion received from different speakers widely different and even inconsistent definitions. When they are asked to vote for the group clinic, they were entitled to know which group clinic it was—the expensive institution suggested by Mr. Dickie, and endorsed by Dr. Lapthorn Smith, or the scheme now in operation under the control of Dr. Hurst, or the group of practitioners sketched by Sir Thomas Horder. His own attitude, continued Dr. Hawthorne, could be defined by submitting two propositions: first, that the spirit and aim of medical practice were entirely different from the spirit and aim of medical research, and that to argue that methods applicable and necessary in the one are prudent and necessary in the other, is obviously misleading; and second, that there was no objection to combination in medical practice, provided only that security was maintained for the welfare of the patient and for the authority and responsibility of the individual medical practitioner.

He proposed to examine briefly the schemes which were put before them at their last meeting. Mr. Dickie's proposition was the erection of a well-designed and well-equipped nursing home and hospital for paying patients, the whole scheme being justified on the ground that it could be made a paying proposition. Mr. Dickie, he said, thinks that medical practitioners ought to be financially interested in such an enterprise, but whether they agreed or differed, the answer did not involve any opinion relative to the issue between group practice on the one hand and personal practice on the other. Medical men might admire Mr. Dickie's schemes, feeling how desirable it would be to have institutions of this kind for their own use, and might sympathise with Mr. Dickie. Next, in the scheme explained as already in practice, Dr. Hurst had been able, by a happy conjunction of events, to organise, free from financial cares, a private hospital, where he could receive and treat patients sent to him for advice and care. In certain directions Dr. Hurst relied upon the coöperation of colleagues for the collection of particular groups of facts, and his enterprise was admirable. None the less, it remained true that the patients were committed to his care, and he was responsible for any advice or treatment given. If this was group medicine, group medicine was already in practice by every practitioner who sent a patient to a neighbouring laboratory for examination for T.B. But was Dr. Hurst's scheme a group? His scheme, if examined by Sir Thomas Horder's elaborate classification, must be marked good, but it was not a group. The third development advocated by various people had been the establishment of an organisation or institution where there would always be on hand an abundant supply of practitioners representing all the talents.

Dr. Hawthorne believed that such an ambition would prove both inefficient and unsound. The proposal was the outcome of an incontestable position—namely, that medical knowledge was so extensive, its details so various, that no single practitioner could pretend to compass it. The tendency of this proposition was to handicap the profession in the pursuit of an ideal, for the ideal medical adviser would be one who is able to deal with his patient as a whole. A sound policy should surely aim at getting as near this ideal as possible, by directing that the training of a medical practitioner, who desires to accept the responsibility of giving advice to patients, should be along the broadest possible lines. But the group system had a tendency in exactly the opposite direction, urging men to be competent, not as advisers of patients, but as examiners of organs. It was said that this group system was the application to private practice of the methods universally adopted in hospital practice, but the hospital patient was not a patient of an institution; he was the patient of an individual, personal, responsible medical practitioner; this medical practitioner was a free man who could request the opinion of a colleague or colleagues on any patient under his care, and, equally, he could refrain from doing so, and in any event he would act upon his own judgment and decision. Again, the hospital officer might request the assistance of an expert in the X ray department or the laboratory, in the observation or collection of a certain group of facts, but the adjustment of these facts to others rested entirely with himself, and the final verdict on the patient remained in the hands of the medical practitioner to whose care he was committed. Still more, the hospital officer was free to develop his own knowledge and skill in any direction and to any extent he thought good, and thus he might, to a steadily increasing extent, free himself from dependence upon the so-called specialist.

---

[1] The opening of the debate was reported in THE LANCET of June 25th (p. 1358).

And with reference to his own development, under the pressure of the rights of colleagues he would be compelled strictly to confine himself to his own rigidly defined department; and where would the limit of this division of department end? The more muddled the department, the greater the restriction upon the scope of each individual member of the group; it would follow that no medical practitioner in the group will be able to act as the medical adviser of the patient. The group system was bad for the practitioner of medicine, or at least for those practitioners of medicine who desired to qualify as advisers of patients. He would not vote for the motion to be presented, but would himself propose a motion to be handed up directly.

Mr. A. W. SHEEN disagreed with Dr. Hawthorne's contention that medical practice is a different thing from medical research. In his opinion every piece of medical practice was a piece of medical research. Patients differed from one another, no two being alike, and it must be remembered that the best kind of research was research on the patient. As to another point made by Dr. Hawthorne, it was obvious that any specialist should be a good general practitioner first, and Mr. Sheen expressed his belief that no specialist ever shut himself in a water-tight compartment. Mr. Sheen disagreed with those speakers at the previous meeting who said that it was not desirable that group treatment should take place in association with hospitals. This statement was perhaps too broad. At the present moment outside interference and State control was dormant in relation to the medical profession, but Mr. Sheen fancied it was only dormant, and that we should hear later of primary health centres and secondary health centres, and that the treatment of private patients at these centres would have to be considered. He reminded his audience that Great Britain includes also outlying parts such as the Outer Hebrides; the problem of the application of group systems to all parts of the country would have to be considered. Vested interests would demand also consideration. An endeavour to disturb nursing homes would lead to difficulties, complications, and troubles. Mr. Sheen said that he personally would like to see the country cut up by counties, big towns, districts, and what not, and be the seat of a series of experiments. He did not like to see any sort of cast-iron system suggested for the whole country, for the circumstances differed so much; the best of these experiments would survive. It might be that in some cases group clinics would arise. In a good many parts of the country there were small hospitals with private wards, where the services of consultants were available, and these in many respects satisfied the requirements of a clinic. In some places the British Red Cross Society had established hospitals, and had put them at the service of the public under certain conditions. In other places hospitals had been started by private generosity. The private wards in St. Thomas's and Guy's were a form of clinic. All these activities were going on, and Mr. Sheen thought we ought to develop them, to enlarge them, and to make clinics of them. He considered that the profession ought to do something more than give the idea of clinics mere lip service. The public had got hold of it; the State had got hold of it, and reform from within was better than reform from without. If we did not try to do something for ourselves, somebody else would try to do something for us. As a result of the old days of the clubs came the National Insurance Acts and the panel practice which, in Mr. Sheen's opinion, was a very unsatisfactory thing. It was obvious that the individual practitioner would never die; he would always be wanted. Mr. Sheen looked forward to the time when the individual practitioner would become far more than he is at present the instrument of preventive medicine. He would go into patients' houses, not to cure them when they were ill, but to prevent them from being ill, and Mr. Sheen imagined it would be a very lucrative business. He would like to see these clinics arising, either as private clinics, or in association with hospitals, large or small. In time these clinics might form part of the student's curriculum, and we should then have a reversion to a better type of apprenticeship. Mr. Sheen would support the resolution because he thought, at all events, it would do no harm, and it would give an impetus to action which, in the end, could be only for the public and professional good.

Mr. C. F. HARFORD said that it was not to discuss the details of schemes but the real principles that the meeting was held; he desired most strongly to support the motion that some sort of group system should be created. Our experiences in connexion with the war had greatly emphasised the need for some sort of group work, and the abolition of the individualism which had been the curse of the profession. It was better to make mistakes than to do nothing. Mr. Harford believed in every kind of reform, but it was a mistake to have cut-and-dried schemes. He believed in the principle of experiment and in attempting to profit from experience gained. Since the war there had been a revision of our hospital system.

A good deal had been heard of municipal clinics; something better in the way of constructive work was wanted. The hospital system, pensions work, clinics for the sick—all these various departments of health activities arose in a very haphazard way. As to private consulting practice, were we to regard Harley-street and Wimpole-street as ideals? The consultants had to treat private patients in a room which was really a gentleman's study, and patients with horrible diseases waited in many cases in the room where the family of the consultant was going to dine, unless he was happy enough to rent a room in somebody else's house. This state of things should not continue.

Mr. Harford recommended a careful study of the Report of the Consultative Council of the Ministry of Health. Lord Dawson's minute was, in his opinion, the most statesmanlike proposal that had been put on paper. The only thing the profession had been able to do was to attempt to pick holes in it. Why should the pathological work and the examination of specimens and testing of urine be done separately for every place and for every centre? The two fundamental difficulties were the ethical question and the economic question. If we could get a group of men who would trust one another a start could be made. Mr. Harford's own department of ophthalmology was practically in the hands of the opticians. A certain number of cases were being seen by the specialist, but the ophthalmic work of the country was being done by the opticians, though it was most important a competent ophthalmologist should make an early diagnosis. Patients all over the country were trusting themselves to the opticians. It was said that there were not enough ophthalmologists to do the work. If this were so it was because of the difficulty experienced by a young man in keeping himself while waiting for a practice. Mr. Harford suggested that the medical schools might register the names of men who would be ready to work together, and thus groups might be started among the younger men.

Dr. STANLEY GEORGE spoke as one engaged in general practice, and did not intend that any of his remarks should be taken as an apologia for the medical practitioners. He pointed out that it was important to the individual patient that as little disturbance as possible should take place in his normal surroundings. A patient slightly ill was treated and restored to health more comfortably and with less disturbance in his private home, but in the graver forms of disease he was better looked after in a well-equipped institution. It was not sufficient merely to improve facilities for dealing with the accidents of life. The ultimate goal was prevention rather than cure. To achieve this goal the energies of all workers must be combined with all possible instrumental aid.

Any scheme of advancement must be such as would assist the practitioner to fulfil his rôle with the greatest advantage. He would not be content to send his patient away, because in this case he had to rely entirely on someone else, but would wish to be in a position to help to make the diagnosis. If private clinics were to be adopted the building should be suitably situated in the districts where they are intended to serve, and should contain ample accommodation. They need not necessarily have elaborate instruments, which were only suitable for very skilled work in university laboratories, but the staff of the clinics should include members of all branches of the profession, and should undertake investigation as to the best methods of prevention and control.

Dr. CHARLES GRAY said that after many years' experience of private practice he would like to say that though we are out first and last for the good of our patients, we are not giving them what we ought to give. The problem remained as to how this was to be remedied. Medicine had extended so enormously that it was quite impossible for any single man to give the patient what he ought to have in any case requiring thorough investigation. Team work was now essential, and also places where patients could be sent for any elaborate investigation which might be required, where also the services of 10 or 20 specialists would be at their disposal if needed. The patient would never do without a personal medical adviser in this country; a single person would have to gather the threads together and advise the individual. But places for residential observation courses were required, and if the profession did not supply these they would be started from outside, without the same benefit to medical men in their relations to patients.

Dr. CARNEGIE DICKSON said that as a consulting pathologist he refused to see any patient who came direct to him, and he was thus already a member of an enormous number of little teams. He also practically, though not absolutely, refused to examine specimens sent to him by doctors unless they also gave some clinical information about the case. The pathologist was not a qualified laboratory assistant, though many apparently considered him such. The consulting pathologist desired to be put into touch with patients, and thus to be enabled to apply his previous experience to every new case. Some medical men had not the least idea how bacteriological specimens should be collected, and about 50 per cent. of the specimens received might be discarded without examination, as far as the good of the patient was concerned. Dr. Dickson held that after various examinations have been made there should be a round-table consultation. He had talked over the idea of group clinics for several years with various groups of men. One little group got to the length of having plans of such a hospital made up; builders' estimates were gone into, and a very powerful group was got together. Much discussion ensued, but the difficulties appeared almost insuperable. In Dr. Dickson's opinion, the difficulties had not all been tackled at the present discussion. He thought most of them were agreed that group work was good and would have to be adopted soon, but the difficulties had not all been faced. The question of remuneration and fees, of course, was always a complicated one. The ordinary fee of the surgeon was a distinct difficulty, because the surgeon often makes a considerably larger fee than the physician upon whose judgment the operation depends. As an independent speaker, Dr. Dickson expressed his opinion that the physician should have a larger share. Another difficulty, was whether there should be financial control over nursing homes. Most of those who had discussed the matter with him were of the opinion that doctors should have no finger in that pie. Those who advocated group clinics did so for the sake of their patients as well as for their own sakes. Dr. Dickson gave examples in support of his contention that the pathologist's life would be rendered much more easy, and that he would be able to render services to the patient which would be much more valuable, under the group system.

Sir THOMAS HORDER said that summarising the debate would almost come to re-reading some of his introductory notes. He thought he need say nothing in regard to those speakers who had laboured the main principles enunciated in the first meeting. He thought that the meetings had been justified. All that those fellows of the Society who had been for some time trying to arrange a debate of this kind had in view was to ventilate the whole question of private clinic systems, and that had been done, even to the extent of some healthy criticism on the part of Dr. Hawthorne. Referring to Dr. Hawthorne's amendment Sir Thomas Horder spoke of Dr. Hawthorne's complaint as to the lack of preciseness in the details of any scheme laid before the meeting. It was not intended to be precise in respect of detail: how could they be precise in matters that had never been discussed? Was it not more likely that the more detailed the scheme had been, the more severely would it have suffered criticism? It had already been pointed out that Dr. Hawthorne's criticism in regard to the distinction between practice and research was an utter fallacy. Was not one modern tendency—which we all believed to be a good one—to combine rather than to divorce practice and research? Was not the recent magnificent work of the Medical Research Committee due entirely to the practice afforded by the war? Could we have had that great contribution to medical research had there been no war. Dr. Flexner, of New York, had told the speaker that more and more did it become obvious that if research was to be helpful it must be combined with and conducted in the same building as practice. Sir Thomas Horder said he had referred to the enormous advantage that group medicine would confer upon the progress of medicine by the facilities of research and additions to medical knowledge which it afforded. Reference had been made to the Mayo Clinic at Rochester. What Sir Thomas Horder had seen in the United States in regard to group practice had damped rather than warmed his ardour. The clinics in the States were so enormous; moreover, they were not run with that philanthropic spirit and freedom from financial interest which we regarded as so important. In his opening remarks Sir Thomas Horder had said that a personal clinic was a clinic in which one man was paramount; he determined what investigations should be added to his initial survey of the case, and he was responsible, therefore, for the diagnosis and treatment. That personal clinic had come; there were two large and successful personal clinics of that kind in this country.

As to a group clinic, each member of the group should be interested in the whole work of the team; it should, for preference, work under the same roof; it should have all the conditions that Dr. Hawthorne referred to. Group clinics of that kind had not yet arrived, and, therefore, it might seem premature that a resolution should be moved which does little more than express a pious opinion. The resolution before the meeting was—

> "That in the opinion of the meeting the time is ripe for the formation of group clinics in this country, and that sympathetic encouragement should be given to them by the profession and by the governing bodies."

Dr. HAWTHORNE, in moving an amendment, wished to dissipate the suggestion that he was opposed to medical research. In scientific research, medical or otherwise, there was only one aim, the discovery of truth. The picture of the group clinic as it was presented at the first meeting had now taken on a somewhat different aspect, and its meaning was still doubtful. It certainly did not mean the scheme which Dr. Hawthorne himself cordially endorsed and favoured—namely, the scheme which was carried into practice by Dr. Hurst. Sir Thomas Horder had said that this was not a true group. The only scheme on which the vote would apparently be taken was the particular scheme which Sir Thomas Horder

S.M.S. MEDICAL COLLEGE,
LIBRARY

defined—that is to say, a group in which no one individual had full responsibility and authority in the case except this vague person called an assessor; instead of the personal relation of an individual practitioner in charge of a sick man it was proposed to offer him the cold and carefully calculated effort of an assessor's summing up. The amendment was a non-committal one, and Dr. Hawthorne knew of no obstacle to the formation of nursing homes, where practitioners might take charge of patients and might secure the assistance of experts, except the financial one. If someone were able to provide two men who were ready and willing to find the necessary money, without any sort of financial gain, then, indeed, we might look forward happily to the development of a suitable institution. Dr. Hawthorne moved the amendment:—

> "That until a precise definition and details are submitted, this meeting prefers to abstain from pronouncing an opinion on any suggested modification of the methods of medical practice."

Dr. M. I. FINUCANE, in seconding the amendment, said that he thought the whole discussion was more or less academic and theoretical, and did not practically apply itself to the general practitioner and his wants. All agreed that team-work was the best, but as Dr. Hawthorne had said, the finance of this matter had not been considered at all. Lord Dawson's scheme was, he thought, a sound one, and he had no doubt that this group system would come about, but no details had been discussed, and if the general practitioner was to be asked for his encouragement some practical scheme must be submitted.

Dr. CHARLES GRAY pointed out that Dr. Hawthorne said there was no objection to starting this clinic system. The great objection was that the present position of the general practitioner, and also the view of the profession at large on this important subject had not been taken, and the object of the meeting was to get the view of a proportion, at any rate, of all the medical practitioners. There seemed to be no alternative between the two schemes. The only alternative was a State system of medicine in which all became paid units.

Dr. FINUCANE asked whether the object of the meeting was to strengthen the Government in promoting a system of clinics. If Sir Thomas Horder's resolution was passed it would be interpreted as the voice of the Royal Society of Medicine.

The PRESIDENT then put the amendment to the resolution to the meeting, and it was lost.

Sir THOMAS HORDER'S resolution was carried.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Question of Federation.

A MEETING of the Irish Medical Committee was [illegible]d in the Royal College of Surgeons, Dublin, on [illegible]ursday, June 30th, Dr. J. M. Day in the chair, when Mr. R. J. Johnstone was re-elected chairman. At the conference which began its sittings in the offices of the British Medical Association on Tuesday last, Mr. R. J. Johnstone and Dr. W. O'Sullivan have been appointed to attend. For two years negotiations have been proceeding with a view to organising the medical profession of Ireland into one association, possibly in affiliation with the British Medical Association; and it is hoped that at a meeting where the overseas branches of the Association and its Federal Committees, the Irish Committee of the British Medical Association, the Joint Organisation Committee (Ireland), and the Irish Medical Association will all be represented, some plan of policy may be arrived at.

The Voluntary Hospitals.

At a meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on July 1st, the following resolution was carried unanimously:—

> "The President and Fellows of the Royal College of Physicians of Ireland can find no justification for the refusal of the Government to give any financial relief to the voluntary hospitals of Ireland, while making a grant of £500,000 to the voluntary hospitals of Great Britain; the grant is intended, not as a provision for the future, but to relieve the hospitals from the position of difficulty to which they have been brought by the abnormal economic conditions of the past few years, conditions which pressed as heavily on hospitals in Ireland as on those in Great Britain. The President and Fellows, therefore, urge upon the Government the justice of making a grant to the Irish voluntary hospitals similar to that promised to the British voluntary hospitals."

A resolution to the same effect has been passed by the Irish Medical Committee.

An Honorary Degree for Prof. Edward Taylor.

The University of Dublin has paid a well-deserved compliment to the Regius Professor of Surgery in conferring on him the honorary degree of Master in Surgery. Prof. Taylor has been connected officially with the School of Physic in Ireland for nearly 30 years, first as examiner in anatomy, then as professor of surgery, and for the past five years as Regius Professor. His treatises on Applied Anatomy and on Operative Surgery are well known to all.

The Senate of Southern Ireland.

Sir William Taylor, K.B.E., a past-President of the Royal College of Surgeons in Ireland, has been nominated by the Lord-Lieutenant a Senator of the Parliament of Southern Ireland, under the provision of the Government of Ireland Act directing that 17 representatives of commerce, labour, and the scientific and learned professions should be nominated. As far as we know, no other medical man has been similarly distinguished.

CZECHO-SLOVAKIA.

(FROM OUR OWN CORRESPONDENT.)

The Hlava Institute.

THE Medical School of Prague has recently opened a new and first-class modern building containing the institutes of pathological anatomy, bacteriology, and legal medicine, with all facilities for teaching and research. It is popularly named Hlava's Institute, after Prof. Jaroslav Hlava, its founder. The building was begun before the war, during which it had to be discontinued. The Ministry of Public Instruction in the new Republic has spared no effort to make the equipment and opening of the institution possible. On the day of opening a very warm ovation was accorded to Prof. Hlava, who is the senior member of the staff of the Medical School in Prague, and has been recently honoured by the French Academy of Medicine, having been nominated a corresponding member.

Czecho-Slovak Watering-Places.

The Czecho-Slovak watering-places are reviving their pre-war reputations. It is not widely realised that Carlsbad, Marienbad, &c., are within the boundaries of the new Republic; direct sleeping-car service has been established from Vienna and Paris, and the Czecho-Slovak authorities have made every effort to facilitate the visits of foreigners to the famous watering-places. Former visitors are now resuming patronage discontinued because of the war.

Infant Welfare.

In the autumn of 1920 Lady Muriel Paget's Mission began to organise infant welfare in Slovakia. Some 11 infant welfare stations have been opened in one of the poorest sections of the province; in coöperation with the League of Red Cross Societies a model children's hospital has been established which will serve as centre for the scheme. The English personnel of the Mission are training local workers to continue its administration when the Mission leaves the country on Jan. 1st, 1922. The work has been very successful so far, and the interest which the Slovak peasants have shown in it has been most encouraging. Dr. Roger P. Stewart, of London, is in charge of the work under the direction of a committee on which Lady Muriel Paget's Mission, the League of Red Cross Societies, and the Czecho-Slovak Red Cross and Ministry of Public Health are represented.

A Medical Strike.

The Czecho-Slovak physicians who serve as medical officers to insurance associations went on strike on May 1st because the associations refused to double the fees paid by an insured person for attendance. The Czech physicians claim that German physicians are receiving such fees from the German associations, and consider themselves entitled to the same. On the other hand, the associations claim that a contract has been made with the physicians up to the end of the year 1921. The strike has already lasted for more than a month, but a speedy settlement is not probable, as the medical profession is well organised and follows very closely the direction of its central organisation. On the other hand, the insurance associations claim that increasing the fees to the physicians would mean financial ruin to the associations, involving a breakdown of the whole insurance system, in which 90 per cent. of the population are included.

Prague, June 15th.

CONTROL OF VENEREAL DISEASES.

Registration of Syphilitics.

A census of the syphilitic fraction of a community may seem an impossible feat, owing to the subterranean character of the disease and the natural disinclination of the persons concerned to figure in such a census. But it is obvious that if such a census were feasible, and kept up-to-date year by year, our knowledge of this disease and our ability to treat it successfully would ultimately be much increased. In a recent paper, Dr. O. Jersild[7] has shown that such a system of registration of the syphilitic is not simply a counsel of perfection, but can be put into effect in a small country such as Denmark, without disconcerting intrusion into the patient's privacy. But it must from the outset be made clear that a system which is perfectly feasible in a country like Denmark may be quite unworkable in a larger and less compact community. In Denmark, where a system of registration of the syphilitic has existed for about half a year, Wassermann's reaction is carried out only in one institute, and under State control. This centralisation of the Wassermann reaction is probably unique, and it would be difficult to overrate the importance of this point. It means that in Denmark, at any rate, the prestige of this reaction has not been undermined by uncontrolled, semi-professional work, and the fact that 41,093 Wassermann tests were made in 1920 at the State Serum Institute, shows that hospital authorities and practitioners make extensive use of the Institute for this purpose.

The machinery for the Wassermann reaction being centralised, it was comparatively easy to evolve a system of registration centring about this reaction. The Wassermann forms have been worded so as to serve the double purpose of a serological report and registration, and the two following principles have been conscientiously followed: (1) Notification should be so organised that it would work almost automatically without compulsion or discomfort to anyone whenever a syphilitic changes his doctor or address; (2) owing to the confidential character of the matter there should be absolutely no chance of personal identification at the central office, where, however, it must be possible to classify the available data accurately and without overlapping. The function of the central office is, in short, that of a telephone centre, enabling one doctor to get into touch with another through a practically automatic and impersonal medium. In time it will be possible for a doctor to learn the subsequent fate of a patient whose disease he treated in its early stage, and neurologists, oculists, surgeons, and physicians will have a guide enabling them to learn not only whether a patient under their care has or has not contracted syphilis earlier in his career, but also the nature of the specific treatment he has received, and other instructive information contained in his registration dossier. As Dr. Jersild points out, registration of syphilitics, if it is to fulfil its functions adequately, should not merely yield statistical information as to the increase or decrease of new cases in a community, but it should also enable the physician to trace the patient's career from the first appearance of a chancre to his death. It should also ensure continuity of treatment, however much the patient may flit between hospitals and from one physician to another.

The five following identification data are entered on the registration form: (1) Sex; (2) birthday and year of birth; (3) the first letter of the patient's surname, a hyphened surname being indicated by the first letter after the hyphen; (4) the date on which the disease was first diagnosed or treated; (5) the name of the physician or institution beginning treatment. By the inclusion of the year of birth of the patient, it will be possible in a few decades automatically to omit from the register a certain number of patients, and thus the register will not be unnecessarily overcrowded. In practice, one shortcoming has already been detected in this system of registration. Syphilologists are apt not to make use of Wassermann's test during the first years after infection, for at this stage a negative Wassermann may prove mischievous, as it may lead to the patient neglecting treatment. The syphilologist also is less dependent than his colleagues on a serological diagnosis. But, unfortunately, his distaste for Wassermann's test early in the patient's career means that many syphilitics evade registration just at the period in their lives when it would be most useful, to themselves in particular. To overcome this difficulty, syphilologists—i.e., heads of V.D. clinics—have been supplied with special registration forms. Although registration has existed only half a year, about 10,000 persons have already been entered on the Serum Institute's register, and its efficiency has been tested in several instances. As an instructive example of the workings of this system, Dr. Jersild refers to a patient whose dossier showed that, though he masqueraded as a new case at Dr. Jersild's hospital, he had been treated there at an earlier date.

A Hostel for Infectious Cases.

The second annual report of the Royal Free Hostel for Women and Girls has just been issued. The hostel was opened in June, 1919, at 24, Gloucester-road, Regent's Park, London, N.W., for the care of girls and women suffering from venereal diseases in an infectious stage. Ten beds are available in rooms of one or three beds. The patients are drawn chiefly from those attending the Royal Free Hospital V.D. Clinic, and are selected by the medical officer to the clinic; but cases from any part of London or the country can be received under certain conditions.

Sir Thomas Barlow is the chairman of the committee of the hostel and the medical members include Miss Aldrich Blake, Lady Barrett, Sir Francis Champneys, Dr. Dorothy C. Hare, Dr. T. S. Higgins, Dr. A. G. Phear, Dr. Ethel Vaughan Sawyer, and Dr. Margaret Rorke. The aims of the committee include not only care with treatment and isolation during the infectious period, but the after-care of those discharged from the hostel. The great importance of after-care is recognised. Even in the most promising cases physical and mental recovery often takes several months, and much help must be given if the individual is to become a useful citizen. The hostel is closely associated with the Royal Free Hospital, but financially it is an entirely independent undertaking. Between April 1st, 1920, and March 31st, 1921, 65 girls passed through the hostel, the average length of stay being 39·19 days.

---

[7] Ugeskrift for Laeger, June 2nd, 1921.

The occupations and disposal of these girls were as follows: the average age of patients was 22·5 years, and their previous occupations were domestic servants, 21; factory or business, 10; clerks, 7; women's services, 7; shop-hands, 6; no occupation, 5; waitresses, 3; prostitutes, 3; married, living at home, 2; companion, 1. Of these 19 returned to former employment, 12 are out of work, 8 have gone to fresh work or training, 4 have been sent to various homes, 3 have returned to prostitution, 3 have been lost sight of, 3 have married, 3 are at home with no occupation. 1 mentally deficient, has been taken under M.D. Act, 1 mentally deficient is with her sister, and 8 are still in the hostel. Patients attend the out-patient department at the Royal Free Hospital twice weekly. In addition, individual medical treatment such as douching is carried out by the sister-in-charge, as instructed by the doctor. Much improvement in general health is noticed while the girls are in the hostel, and their increase in weight is often astonishing. The attendance records at hospital for hostel patients are satisfactory. A few cases admitted from hospitals other than the Royal Free continue to attend their own clinics. Every girl is in the hostel by her own choice, and is free to leave if she will. Most settle down quickly, but some are unhappy and depressed at first, or are physically too ill to take an active part in the life of the home. The fundamental idea in the ethical teaching given is to develop such principles as the girls already possess, and to lead their often distorted views of life and morals into right channels. Open discussion on questions of religion and social conduct is encouraged. The lighter work of the house is done by the girls, under the supervision of the house matron. In the afternoons they rest or go out, and in the evenings they make their own clothes, or learn handicrafts, such as basket-making or raffia work. The staff consists of the sister-in-charge, who is a fully trained nurse, and two assistants, a house matron and a kitchen matron. Of the 95 patients who have left the hostel since it was opened, definite news has been received of 92. The cases may be grouped as follows: doing well at present, 57; doubtful at present, 18; no good at present 10; lost sight of, 3; in homes needing permanent supervision, 5; certified under Mental Deficiency Act, 2. Of those classed as "doubtful" or "no good," several were only in the hostel a few days, and owing to their harmful influence on the other inmates, were returned to the senders or removed to the infirmary. It is regarded as impossible to furnish a report which shall be permanently accurate. On the whole, however, those considered as satisfactory have remained so, and of [illegible] rest some have become satisfactory, and some [illegible] the most unpromising have changed their mode [illegible]fe, at least temporarily.

The expenses for the year have amounted to [illegible]026. The receipts (which include the balance in hand at the beginning of the year of £201) amount to £1302. The estimated outlay for the coming year is £1120. The London County Council have recommended that the Ministry of Health should make a grant of £100, an increase of £100 on the previous year's grant. Patients' payments may be expected to bring in £100. This leaves a sum of £620 to be obtained in subscriptions and donations. The committee express their conviction that if a wider public could realise the great importance of the work done, sufficient financial help would be forthcoming. Medical practitioners who are desirous of securing the admission of a patient to the hostel are invited to refer the case with a note to the medical officer of the Royal Free Hospital V.D. Clinic. Patients from other hospital clinics in the district are admitted and arrangements made for them to continue under the care of their own medical officer. Applications for vacancies should be made to the Almoner, Royal Free Hospital, Gray's Inn-road, London, W.C.1. The most suitable cases for admission to the hostel are young girls. Married women, professional prostitutes, or remand cases are not usually suitable. Cases of pregnancy are not admitted after the early months. Patients are kept in the hostel, if possible, until their condition becomes non-infectious, and suitable arrangements have been made for their return to work, or to their families. The circumstances of patients are inquired into and they are required to contribute towards the cost of their maintenance if in a position to do so, but no patient is refused on grounds of inability to pay. A maximum charge of 35*s.* per week is made; the average charge is 15*s.* Further information regarding the hostel may be obtained on application to the Almoner, Royal Free Hospital, Gray's Inn-road, London, W.C.1, or the Hon. Secretary, 6, Drayton-gardens, London, S.W.10.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieuts. (ret.) to be Surg. Lieut.-Comdrs. (ret.): A. L. Robinson, G. A. Jackson, and W. L. Cowardin.

Actg. Lieuts. to be Lieuts.: H. G. Marsh, P. R. Enright, and F. W. Langford.

ROYAL ARMY MEDICAL CORPS.

Capt. and Bt. Maj. W. F. Christie retires, receiving a gratuity, and is granted the rank of Maj.

Capt. W. Walker and Capt. P. J. Ryan relinquish the actg. rank of Maj.

Capt. H. A. Hill, from R.A.M.C. Spec. Res., to be Lt., with the temp. rank of Capt.

Officers relinquishing their commns.:—Temp. Capts. retaining the rank of Capt.: W. M. Muirhead, F. Whitby, H. Abernethy, and B. N. Sinclair.

SPECIAL RESERVE OF OFFICERS.

Capt. R. Magill to be Maj.

TERRITORIAL FORCE.

Maj. W. Bowater to be Lt.-Col. and commd. 1st S. Mid. Fd. Amb.

Capt. A. P. Thomson resigns his commn. and is granted the rank of Maj.

Capt. W. J. Lacy-Hickey and Capt. J. G. Hayes resign their commns. and retain the rank of Capt.

Lt. J. P. Kitson (late R.A.M.C.) to be Capt.

The King has conferred the Territorial Decoration upon the undermentioned officers: Lt.-Col. D. L. Hamilton, 2nd H. Counties Field Amb.; Lt.-Col. C. L. Isaac, 3rd Welsh Field Amb.; Maj. G. R. Wilson, attd. 8th Bn. Manch. R.; Maj. D. H. Weir, attd. 4th Bn. North'd. Fus.; Maj. W. F. McAllister-Hewlings, attd. N. Mid. A.S.C. (ret.); and Maj. E. L. Rowse, 1st Lond. Fd. Amb.

TERRITORIAL FORCE RESERVE.

Lt.-Col. (Bt.-Col.) C. J. Jacomb-Hood, having attained the age limit, is retired, and retains his rank with permission to wear the prescribed uniform.

The King has conferred the Territorial Force Decoration upon Col. Sir R. H. Luce, K.C.M.G., V.D.

DEFENCE FORCE.

Temp. Capts. relinquishing their commns.: G. M. Campbell and W. T. Briscoe.

ROYAL AIR FORCE.

Flight Lts. to be Squadron Leaders: D'Arcy Power, J. Rothwell, K. Biggs, and A. J. O. Wigmore.

Flight Lts. to be Hon. Squadron Leaders: A. E. F. F. Huntsman and G. D. Kerr.

INDIAN MEDICAL SERVICE.

Maj. J. J. Robb to be Lt.-Col.

Temp.-Lt. H. R. Rishworth (since relinqd. his commn.) to be temp. Capt.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—Frank M. Allchin, Stanley Colyer, Geoffrey Fildes, Alexander Flett, Harry Gardner, Wilfrid Garton, Arthur H. Laird, Traian Leucutia, Dalziel B. McGrigor, David M. Muir, Henry E. Oakeley, Pieter Johann Olivier, Bertram Shires, Hendrik Willem Johannes van Dijken, John D. White, George D. Whyte, William P. G. Williams, and John R. Wylie.

Part II., Radiology and Electrology.—Frank M. Allchin, Stanley Colyer, James P. S. Dunn, Geoffrey Fildes, Harry Gardner, Wilfrid Garton, Arthur H. Laird, Traian Leucutia, Dalziel B. McGrigor, David M. Muir, Henry E. H. Oakeley, Pieter Johann Olivier, Bertram Shires, Hendrik Willem Johannes van Dijken, John D. White, George D. Whyte, W. P. G. Williams, and John R. Wylie.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates were successful:—

EXAMINATION FOR DEGREE OF M.CH.

George Perkins, Hertford.

SECOND EXAMINATION FOR DEGREE OF B.M.

Materia Medica and Pharmacology.—Murray McCheyne Baird, New; *Owen D. Ballinger, University; Weldon* Champneys, Oriel; Edward F. Chapman, Magdalen; Harry N. K. Elphick, New; Robert Van Buren Emmons, New; Reginald V. Facey, Brasenose; Humphrey A. Gilkes, Christ Church; John R. B. Hern, New; Robert F. Johnstone, St. John's; *Cyril R. Lane, Pembroke; Walter J. E. Lupton,* New; Peter H. Martin, New; James D. Mills, Lincoln; Eric H. Watkins, Hertford; Norah E. Bodkin, Society of Oxford Home Students; Katharine M. Hodgkinson, Somerville; and Constance M. Ottley, Society of Oxford Home Students.

Pathology.—John W. Alden, non-collegiate; Owen D. Ballinger, *University; Walter H. Butcher, St. John's; Weldon Champneys,* Oriel; David S. Davies, Magdalen; John H. Fletcher, Trinity; Duncan G. Leys, Balliol; Horace D. Pavière, Christ Church; Maurice E. Shaw, New; Eric H. Watkins, Hertford; Bernard W. Williams, Exeter; and Norah E. Bodkin, *Society of Oxford Home Students.*

Forensic Medicine and Public Health.—Thomas H. Cathrall, *Trinity; Malcolm H. Mackeith, Magdalen; Henry A.* Osborn, New; Maurice E. Shaw, New; Cecil H. Terry, Balliol; Clement J. L. Wells, St. John's; and Dorothy J. Collier, Society of Oxford Home Students.

Medicine, Surgery, and Midwifery.—Walter H. Butcher, St. John's; David G. T. Cross, St. John's; Charles F. T. East, New; William E. Hayes, New; Edward G. T. Liddell, *Trinity; Malcolm H. Mackeith, Magdalen; and Howard L.* Rayner, Balliol.

Mr. P. H. Martin, New College, has been elected to the Theodore Williams Scholarship in Anatomy. The scholarship is tenable for two years, and is of the annual value of £50.

UNIVERSITY OF ST. ANDREWS.—The following candidates have been successful in examinations recently held:—

THIRD PROFESSIONAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Medical Jurisprudence and Public Health.—Frank E. Anderson, Colin R. Baxter, Archibald J. Campbell, Cora C. Campbell, Gurbaksh Chawla, David C. Clark, James Craigie, William M. Cumming, Jean M. Davidson, Violet C. Dobbie, Ruby N. Foggie, Donald S. Greig, Charles R. Henderson, Norah M. Lindberg, Norman McLeod, Jean H. Morton, Janet Muirhead, Robert Norrie, Sydney S. Ogilvie, Alan Pride, Alexander B. Richardson, Agnes H. T. Shepherd, Lucy C. Simpson, Bhagwant Singh, Edith M. D. Smith, Blanche D. S. Spence, Janet O. Stephen, Arthur Tateson, William Thomson, Frances H. Watson, and Thomas Wilson.

Materia Medica and Therapeutics.—Monawar K. Afridi, George F. G. Batchelor, Colin R. Baxter, *Norman T. Brown,* David R. Cameron, James Dallas, Ellen Douglas, Howard H. A. Elder, Andrew A. Finnigan, Jessie H. Fitchet, John R. Graham, Donald S. Greig, George S. Halley, Leigh H. Henderson, Robert A. Henry, James A. G. Keddie, Lena E. Low, *James R. Miller, John R. Murray,* James W. Napier, Margaret C. K. Patterson, James A. Robb, Peter C. Robertson, David Rushton, Blanche D. S. Spence, Jessie R. Watson, James M. Webster, and Margaret P. M. Wilkie.

Pathology.—Monawar *Khan Afridi, David S. Anderson,* George F. G. Batchelor, Colin R. Baxter, Thomas F. Black, Norman T. Brown, David R. Cameron, Gurbaksh S. Chawla, James Dallas, William F. Dorward, Ellen Douglas, Howard S. Edwards, Howard H. A. Elder, Andrew A. Finnigan, *Jessie H. Fitchet, John R. Graham, Donald S* Greig, George S. Halley, Jean T. Harris, Alexander Henderson, Leigh H. Henderson, Robert A. Henry, Lilian A. M. Johnston, James A. G. Keddie, Gordon D. Laing, Jeannie P. Laird, Lena E. Low, Francis McLagan, Robert S. Melville, James R. Miller, Hermina M. Morrison, James W. Napier, John E. Overstead, Margaret C. K. Patterson, Peter C. Robertson, David Rushton, Isabella Sim, David B. *Soutar, Gertrude J. Sturrock, Ian C. Thomson, Jessie R.* Watson, James M. Webster, and Margaret P. M. Wilkie.

FOURTH PROFESSIONAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Medicine.—George G. Buchanan, Katharine M. Campbell, Georgina S. Craig, David W. Dawson, Vyvyan S. Ewing, Phyllis Fleming, Annie A. Fulton, Alexander H. Harkens, L. Jacobs, Isabella D. Kilgour, Nona S. Lesslie, Elizabeth W. MacVicar, Isobel M. Mansie, Ronald S. Paton, John D. Stewart, Christina J. Thomson, Margaret L. Tod, and Margaret H. R. Young.

Surgery.—Georgina S. Craig, David W. Dawson, Vyvyan S. Ewing, Phyllis Fleming, Annie A. Fulton, Alexander H. Harkens, Isabella D. Kilgour, Katharine D. Macfarlane, Elizabeth W. MacVicar, George J. Murray, Ronald S. Paton, John D. Stewart, Christina J. Thomson, and Margaret L. Tod.

Midwifery.—Georgina S. Craig, David W. Dawson, Vyvyan S. Ewing, Annie A. Fulton, Alexander H. Harkens, L. Jacobs, Isabella D. Kilgour, Nona S. Lesslie, Katherine D. Macfarlane, Elizabeth W. MacVicar, Isobel M. Mansi, George J. Murray, Ronald S. Paton, James N. D. Smith, John D. Stewart, Christina J. Thomson, Margaret L. Tod, *and Margaret H. R. Young.*

UNIVERSITY OF DURHAM: *Faculty of Medicine.*—At the Convocation held on June 28th, the following degrees were conferred:—

Doctor of Medicine.—Joseph W. Craven, M.B., B.S.; Roger Errington, M.B., B.S.; Harold M. Leete, M.B., B.S., B.Hy.; William K. Russell, M.B., B.S.; James C. Spence, M.B., B.S.; and Hans W. Walther, M.B., B.S.

Doctor of Medicine for Practitioners of 15 Years' Standing.—Stanley Bott, M.R.C.S., L.R.C.P.; Harold Chaffer, L.R.C.P. & S., L.F.P.S. Glasg.; and Frederick A. L. Hammond, M.R.C.S., M.R.C.P., D.P.H.

Master of Surgery.—Henry Evers, M.B., B.S., F.R.C.S.; and William Reynolds, M.B., B.S. (in absentia).

Bachelor of Medicine and Bachelor of Surgery.—Samuel E. H. *Anderson, Thomas H. Bates, John S. Brodgon,* Edward T. Colville, Oliver Colville, John J. N. Daniels, Dorothy A. Dixon, Dorothy F. Elliott, Eskander Girgis, Geoffrey A. Haydock, Roland Hewitson, Reginald A. Hickley, Donald F. Hocken, William E. D. Hodgson, Eustace V. Howard, M.A., *Hilda Lodge, Morris Mickler, Lionel Myers, Joan W. Nicoll,* Robert J. Perring, Sydney T. Pybus, Mary F. Richardson, and William C. Wardle.

Bachelor of Surgery.—John E. Basham, M.B.

Bachelor of Hygiene.—Charles N. Armstrong, M.B., B.S. Durh.; Edith C. M. Jones, M.B., B.S. Durh.; Melville D. Mackenzie, M.D. Lond.; and Thomas N. V. Potts, M.B., B.S. Durh.

The following received the Diploma in Public Health (D.P.H.):—

Charles N. Armstrong, M.B., B.S. Durh.; Edith C. M. Jones, M.B., B.Sc. Durh.; Francis J. Lidderdale, M.B., B.S. Durh.; Melville D. Mackenzie, M.D. Lond.; Thomas N. V. Potts, M.B., B.S. Durh.; and William O. F. Sinclair, M.B., B.S. Durh.

RESEARCH DEFENCE SOCIETY.—The annual general meeting was held on June 29th, Lord Lamington, the President, in the chair. The President spoke briefly on the work of the Society, after which Lord Knutsford, chairman of committee, moved the adoption of the annual report in which a satisfactory account is given of the work of the past year. The number of articles and letters in the newspapers, and of pamphlets or leaflets distributed, has been large. The quarterly reports of the Society are now sent not only to members, but to the public libraries, and may be bought by anybody for 6d. from Messrs. Macmillan and Co. A number of addresses and lantern lectures have been given. The falling off in the number of debates is not regretted as these are not considered of much educational value. Sir Walter Fletcher, Dr. D. T. Harris, and Miss Burgiss-Brown have become members of committee, of which Mr. Stephen Paget has been appointed vice-chairman on his resignation of the hon. secretaryship. Lady Horsley acted as hon. secretary for some months, and in May Dr. D. T. Harris was appointed hon. secretary. During the past year some new members have been gained, but the total membership is, of course, less than it was in 1914, when it was about 5000. Some have died, some have been unable to keep up their subscriptions, and some have felt that the Society has won all down the line, and that nothing is left to fight for. But the activity of the opponents of medical research still continues, and the Society is the only one organised for the special purpose of meeting it. The chief need of the Society is a larger membership and more money for publishing, for distribution of literature, and for lectures. The subscription is 10*s*.

After the report had been received and adopted Dr. H. H. Dale, F.R.S. read a paper on the Work of the National *Institute for* Medical Research, which appears on p. 112 of our present issue. The meeting concluded with a vote of thanks to Dr. Dale, proposed by Sir Leonard Rogers, F.R.S., and seconded by Prof. W. Bayliss, F.R.S. Further information on the work of the Research Defence Society can be obtained on application to the Secretary, 11, Chandos-street, Cavendish-square, London, W. 1.

Society for the Study of Inebriety.—The next meeting of the Society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, July 12th, at 4 P.M., when Dr. W. A. Potts will open a discussion on Alcohol and Alcoholism in Relation to Mental Deficiency. The subscription for the Session 1921-22 was due on April 1st, 1921, and this subscription, together with any yet unpaid for the past session of 1920-21, should be forwarded at once to the Hon. Treasurer. Members and associates, and other friends of the Society, are invited to make a special contribution to the Reserve Fund in order to meet the heavy expenditure now entailed in publishing the official journal, and carrying on the work of the Society. All subscriptions and donations should be forwarded to the Hon. Trasurer, Mr. Arthur Evans, M.S., F.R.C.S., 28, Devonshire-place, London, W.1.

Harveian Society.—The annual dinner of this Society was held on June 22nd at the Café Royal, Dr. G. de Bec Turtle, the President, in the chair. Sir D'Arcy Power proposed the toast of the Harveian Society and congratulated the members on the fact that throughout the 90 years of its existence it had never been in a more flourishing state than it was to-day. The President responded to this toast, recalling the foundation of the Society by ten medical men in September 1831. The period of its foundation was pregnant with advances in medical science. The practical uses of auscultation were being discovered, and the connexion between dropsy and albuminuria and kidney disease had only recently been established by Richard Bright. Dr. Marshall Hall, who demonstrated reflex action of the spinal cord in 1833, was one of the founders of the Harveian Society. The President spoke of his predecessor Dr. Leonard Guthrie, who had taken the chair in 1913 at the last dinner of the Society, and of the loss sustained by the Society and his medical colleagues in his death. Sir James Dundas-Grant then proposed the toast of kindred societies and guests, to which Sir John Bland-Sutton and Mr. H. Curtis Bennett, K.C., responded.

The late Dr. P. E. Wallis.—Percy Evershed Wallis, who died at East Grinstead on June 26th, had been medical officer of health for the urban district since the year 1889, and in addition held a number of other public appointments in the town and district. Born at Hartfield in 1852, he was educated at Epsom College and King's College, London, and received his medical training at Guy's Hospital. Here he was vice-captain of both the cricket and football teams, and all his life took a deep interest in the summer and winter games. He took the L.R.C.P. Edinburgh and L.M. diplomas in 1877 and became M.R.C.S. England in the same year. At East Grinstead, where the bulk of his professional life was spent, he was regarded as a careful practitioner, and was admired and respected by all for his professional skill, his sound judgment, and his intellectual honesty. He suffered a great blow by the death of his only son, an officer in the Royal Sussex Regiment, in the war, and again by the death of his wife two years ago. He leaves two daughters.

Metropolitan Hospital Sunday Fund.—The following are among the amounts received at the Mansion House. The total to date is about £50,000:—

	£	s.
Strathcona and Mount Royal	5000	0
. Tetley, £1,000; Mrs. H. G. Tetley, £500; n of Mr. and Mrs. H. G. Tetley, £1,000 ..	2500	0
.. ..	1000	0
th American Bank	525	0
Bank, Ltd.; London County Westminster Parrs' Bank; National Provincial and Union k of England .. .. .. each	500	0

Lloyd's Health Insurance Society.—The ninth annual general meeting of this Approved Society was held in the Committee Room at Lloyd's on June 24th. Sir John Luscombe (President) in reviewing the Society's position, said that in looking backward over the ten years' operation of the National Insurance Act it must be admitted that on the whole national health insurance had been a great success. Since the inception of the Act no less than £65,000,000 had been paid in cash benefits; the recent valuation of Approved Societies had shown its financial basis to be sound, and it had been loyally accepted by both employers and employed. There must be an inherent rightness in the principle of this Act, which had stood the strain of nine of the most troubled years of British history. The administration of their own Society continued to be carried on in a very efficient manner; the result disclosed in the valuation report stating the position on Dec. 31st, 1918, was surprisingly good; a surplus of £7451 on the first five years' working was shown.

British Hospitals Association.—At the annual meeting of this Association, held at the Royal Infirmary, Manchester, on July 1st, Sir Arthur Stanley presiding, the principal subject of discussion was the finance of British Voluntary Hospitals, more especially concerning the help which it is hoped to secure out of the surpluses of approved societies. It is difficult to say what proportion of the population are treated in the hospitals every year; the figure was originally put at 2 per cent. but the Association puts it at 5 per cent. If, said the president, the 95 per cent. who do not require hospital treatment were insured, as it were, against it, the hospitals should get a good income. It has been suggested that the approved societies should contribute a guinea a week for each member treated in the hospital, which, however, is far below the cost. It is not likely that the hospitals will get any of the surplus accumulated by the approved societies in the past, which the hospitals had helped to accumulate, but the President suggested that there was no reason why they should not try to get some of the surplus which the societies would amass in the future. Mr. F. J. Hazell, Superintendent of the Royal Infirmary, said that they were willing to take patients at that institution at a guinea a week, which is twice as much as they ordinarily get. Finally, the meeting authorised the Council of the Association to continue its negotiations with the approved societies and to endeavour to induce the societies to contribute a central fund from which grants would be made to the hospitals. The President, who was re-elected, said the Government departments and everyone concerned had put it definitely on record that every effort ought to be made to preserve the voluntary system for hospitals and not to put them on the rates or into the hands of the State.

Treatment of the Insane.—Professor George M. Robertson, physician-superintendent of the Royal Edinburgh Asylum at Morningside, at the weekly luncheon of the Edinburgh Rotary Club on June 23rd, said that there were three great impediments to progress in the care of those affected in mind. Desired improvements were limited by financial means; there was a want of initiative and a dearth of ideas. The General Board of Control, which supervised the administration of mental hospitals, had, however, been so successful that it was truly described as having a European reputation. The third impediment was that of the out-of-date and archaic laws under which they were required to work. The strict laws against abuses were, no doubt, necessary when they were introduced, but such precautions were now not only quite unnecessary, but were an actual source of injury to patients. The mental patient suffered from an illness like any other illness, and this required medical treatment, not legal commitment. Owing to legal formality it often happened that a patient could not receive treatment in a mental hospital in the early stages of his illness, and time was lost at a point when there was most hope of effecting a recovery. These antiquated laws operated most harshly on the poor, who could not in practice avail themselves of voluntary treatment, because the Government grant in aid, which in part helped to pay for the maintenance of poor patients in mental hospitals, was not given by the Treasury to the parish unless the patient had actually been certified insane and committed by a Sheriff. Another legal enactment, illogical and absurd as well as hurtful, was that the Lunacy Law of Scotland permitted a patient with mental symptoms to be treated temporarily, without being certified insane, in any place except a mental hospital. The patient might be placed in most unsuitable surroundings, ill-attended by untrained persons, and the fact of his treatment concealed from the knowledge of the officials of the Board of Control—all according to law. It was, however, illegal for the same patient to be placed in a hospital specially designed for the treatment of mental diseases unless he was branded as a lunatic. Two simple alterations would be (1) the enactment of a law giving permission for treatment in a mental hospital of any patient suffering from a recent attack of mental disorder, for a period not exceeding six months, on simply notifying the Board of the fact; and (2) a clause giving the Government grant in aid to poor patients chargeable on the rates, without the formality of certifying them as lunatics.

INFANT WELFARE CONFERENCE.—The second English-speaking conference on infant welfare promoted by the National Association for the Prevention of Infant Mortality and the National Baby Week Council was opened at the Central Hall, Westminster, on July 5th. Lord Astor presided, and in his opening address emphasised the need for economy in child life as well as in money. Dr. Janet Campbell read a paper on Maternity Homes, in which she explained that the science of midwifery had lagged behind other branches of medicine in recent years and that better conditions were needed for the conduct of cases in labour. At the afternoon session Mrs. Cyril Smithett read a paper on Residential Provision for Mothers and Babies. The Child Welfare Exhibition was opened by Sir Alfred Mond, who dwelt on the advantages to be gained by bringing home to people visually, as in that exhibition, the proper methods of rearing infants.

CHILD WELFARE FÊTE.—An effort is being made to raise money for the promotion of infant and child welfare by a fête to be held on July 16th in the Royal Hospital Gardens, Chelsea. The promoting body is the Central Council for Infant and Child Welfare, which was brought into existence through the efforts of the Joint Council of the Order of St. John and the British Red Cross Society for the purpose of promoting the well-being of children from the ante-natal period up to the age of 16. The Central Council is formed from 13 bodies, which have more or less identical aims, being concerned with mothercraft, the welfare of healthy and sick babies, the care of invalid and crippled children, the provision of day nurseries and convalescent and holiday homes, and the training of volunteers in all branches of the work, and Sir Arthur Stanley is its chairman. Offers of gifts of saleable articles for the fête are solicited and should be sent to Miss Wilson, Secretary of the Central Council for Infant and Child Welfare at 20, Berkeley-street, London, W.

DONATIONS AND BEQUESTS.—During the last six months contributions have been made to the Christie Hospital, Manchester, from the executors of the late Miss Margaret Gerard (£1280) and of the late Miss Margaret Cunliffe (£500) and of the late Mrs. Mount (£30). The late Mr. W. Sutcliffe left a legacy of £200 to this hospital and Dr. J. Howie Smith of Stockport of £100.—The Chelsea Hospital for Women has received from an anonymous friend the sum of £100 to the General Fund and £100 to the Convalescent Home Fund.—The late Captain Roger Grenville Peek bequethed £1000 to the London Hospital.—The late Mr. Charles Wills, J.P., of Bristol, left by will £100 each to the Bristol General Hospital, and the Bristol Royal Infirmary; £50 each to the Medical Mission in Red Cross-street, the Bristol Royal Hospital, and the Blind Asylum, and the Orthopædic Hospital and Home for Crippled Children.

MANCHESTER UNIVERSITY GRADUATION CEREMONIAL.—The Vice-Chancellor on July 2nd conferred nine honorary degrees on distinguished persons. Amongst them were Mr. R. Kidston, distinguished for his investigations on palæobotany, Prof. C. S. Sherrington, F.R.S. and Waynflete Professor of Physiology at Oxford, who received the degree of Doctor of Science, and Prof. Elliot Smith, F.R.S., formerly Professor of Anatomy in the University, the degree of Litt.D. The Vice-Chancellor stated that there were nearly 2900 students on the books (500 in the Faculty of Technology), of whom 600 were women. The appeal fund has now reached £220,000; the efforts to increase it were suspended during the industrial crisis. It was most desirable that monetary local support should be given to the University, as the amount of money assigned to each University from the Government grant by the University Grants Committee will in future be proportioned to the amount of local support which it receives. Thus, if the University appeal for £500,000 had been met by a response of £400,000 by the local community instead of £200,000, the University would have received twice as large an additional grant from the Committee. If, said the Vice-Chancellor, the half million were raised, this plus the increased Government grant would "enable us to pay our staff adequately, to house our students, and meet all the needs for which we sought help. Instead we are being faced with an annual deficit of not less than £5000 in carrying on our present curtailed activities."

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JUNE 28TH.

Public Health (Officers) Bill.—Dentists Bill.

THE Public Health Officers (No. 2) Bill was read a second time.

The Dentists Bill was read a third time and passed.

TUESDAY, JULY 5TH.

The Public Health (Officers) (No. 2) Bill passed through Committee without amendment.

HOUSE OF COMMONS.

TUESDAY, JUNE 28TH.

The Blind Population of India.

Mr. GRUNDY asked the Secretary for India the approximate number of blind people in India; whether there was any legislation in force for their treatment and care; and, if not, whether he would make recommendations on this subject to the Government of India.—Mr. MONTAGU replied: At the Census of 1911, there were 175,214 blind males and 173,133 blind females in British India. There is no special legislation applicable solely to blind persons, nor has the need of such legislation become apparent. Dispensaries, stationary and travelling, are available throughout British India, where treatment is given gratuitously to all poor persons; and cataract and other eye operations form one of the largest and most widely appreciated branches of their work. In the United Provinces, for example, 12,326 in-patients were treated during 1919, and 591,229 out-patients, for eye diseases.

Health Safeguards in Slate Quarries and Mines.

Major BREESE asked the Secretary of State for the Home Department if it was intended at an early date to formulate fresh regulations for safeguarding the health and providing against accidents of men employed in the slate quarries and mines of the United Kingdom.—Mr. BRIDGEMAN replied: The revision of the existing regulations has already been taken in hand and will be completed as quickly as possible, having regard to the paramount claims of the work put on the Department by the prolonged stoppage of the coal-pits.

Report of Committee on Pensions.

Mr. PENNEFATHER asked the Minister of Pensions whether the Committee appointed by him some seven months ago had yet reported; if so, whether the report contained recommendations or suggestions in the direction of greater efficiency and economy in administration and greater satisfaction to pensioners; and whether the report would be published and an opportunity of discussing it provided before the House rose.—Major TRYON replied: The report of this Committee is now with the printers; and, as Chairman of the Committee, I hope to submit our recommendations for my right honourable friend's consideration within the next few days.

WEDNESDAY, JUNE 29TH.

Hospitals and the Key Industries Bill.

The House went into Committee on the Safeguarding of Industries Bill, Mr. JAMES HOPE in the chair.

Mr. KILEY moved an amendment to Clause 1 (Charge of Customs Duties on Goods in Schedule), the object of which was to postpone the operation of the Bill until January 1st, 1922. —Dr. MURRAY said while the amendment had been moved entirely from an industrial and commercial point of view, he thought the Government ought to remember that the hospitals of the country had been in dire straits ever since the Armistice. Their laboratories had got out of gear, and there was an almost universal need for new equipment. One of the tragedies of the last three years had been the fact that the hospitals had not only been unable to minister to the number of patients who required their aid, but had been unable to procure the instruments, glassware, and other equipment of that kind which they required in the interests of their patients. The Government had announced that they were going to give £500,000 to the hospitals, but if they did not get time to re-equip their laboratories, and re-stock their instrument departments, nearly the whole of that £500,000 would be used up in extra expense in that direction, so that the Government would be robbing Peter to pay Paul, and this £500,000 would be a sham and a delusion and a snare. This Bill was going to hit our hospitals very hard, and the governors of those institutions should be given sufficient time to replace their equipment. That could not be done in six months. They did not yet know how much of this money they were going to get, and unless they could carry out the whole thing before January all this money would be practically useless.—Major BARNES said that one could not go up and down the streets of London without seeing at every hospital bills notifying the closing of beds and the reduction in the number of out-patients. At a time when every charitable institution in this country was crying out to the charitably disposed for funds for, perhaps, the most sacred cause to which funds could be devoted—the alleviation of human suffering—the Government were bringing in a Bill to make it more difficult and more expensive to alleviate that suffering.—Mr. A. M. SAMUEL said no human being would do anything to clog the ability of a hospital to be properly equipped, but the hon. Members who had spoken had not given the Committee a single proof that the necessary instruments were not in the shops or warehouses of this country already to be bought if the hospitals needed them.—Col. PENRY WILLIAMS said that only the other day they saw an account in the press of a new scientific instrument which had been acquired by the West London Hospital for the treatment of cancer. It cost £2000. Under this Bill £600 odd would be added to its cost to the people who hoped to benefit by this treatment. Was that the policy of the Government? He believed that had it the money each hospital would acquire one of these new instruments. If they were given the extra six months, and they had £500,000 for the equipment of their hospitals, a large amount of human suffering would be saved.—Mr. BALDWIN (President of the Board of Trade) contended that the community had had ample notice of this Bill. He was quite unable to accept the amendment.

On a division the amendment was negatived by 189 votes to 77.

Deaths from Vaccination.

Mr. WATERSON asked the Minister of Health whether letters of inquiry were still addressed to medical men who certified deaths as due to vaccination; and, if so, how many of such letters had been sent in regard to such certificates during the past ten years.—Sir A. MOND replied: The answer to the first part of the question is in the affirmative; 20 such letters have been sent during the past ten years. It is also the practice in these cases for a medical officer of the Ministry to make personal inquiries into the circumstances.

The Occupational Census.

Mr. ROSE asked the Minister of Health if, in view of the urgent public need of information as to our industrial population and the fact that the full occupational census had usually taken from three to four years to compile in detail, he would take measures to issue as early as possible an approximate or round figure occupational census, showing the rough totals of occupied and unoccupied persons, and the allocation of the occupied population amongst the industries.—Sir ALFRED MOND replied: As no occupational figures for the whole country, however approximate, could in any event be furnished until every individual return has been examined and classified, it does not appear that advantage is to be gained by any departure from the present programme. It is intended to prepare and publish the occupational and certain other census statistics by counties. The earliest issue may be expected in a few months, and the whole will, it is hoped, be completed in two years. The importance of these figures is recognised, and every effort will be made to expedite their issue.

Administration of Dundrum Asylum.

Mr. HAYDAY asked the Chief Secretary to the Lord Lieutenant of Ireland who was responsible for the administra[illegible]on of the Dundrum State Asylum, in view of the fact that [illegible] staff worked over 12 hours a day, and that repeated [illegible]mises made many months ago to improve their general [illegible]nditions of service had not materialised.—Sir H. GREENWOOD replied: Arrangements have already been agreed to which should enable the hours of work of the staff of this institution to be substantially curtailed. The administration of the asylum is in the hands of the governor, subject to the usual administrative and financial control.

Army Statistics.

Major BROWN asked the Secretary for War what were the total numbers, all ranks, of the Army Service Corps, Royal Army Medical Corps, Royal Army Ordnance Corps, Royal Army Veterinary Corps, Royal Army Pay Corps, Corps of Military Accountants, Army Educational Corps, and Army Dental Corps in the year 1913-14; and what was their estimated total for the year 1921-22.—Sir L. WORTHINGTON EVANS replied: Excluding the Army in India, the total numbers in the corps mentioned in 1913-14 were 14,609, and the estimated total for 1921-22 is approximately 20,569.

New Hospital Commission.

Mr. LEONARD LYLE asked the Prime Minister what steps, apart from the grant of money towards voluntary hospitals, he proposed to take to give effect to the recommendations of Lord Cave's Committee dealing with the improvement of the financial position of these institutions.—Sir A. MOND (Minister of Health) replied: I am now taking steps to appoint a Hospital Commission which will be responsible for the establishment of Local Voluntary Hospital Committees for the distribution of the State grant and for assisting in raising fresh revenue and in combining and co-ordinating the activities of the hospitals generally on the lines recommended by Lord Cave's Committee. The other recommendations of that Committee, some of which would require legislation, are still under consideration.—Mr. LYLE: In view of the fact that the Finance Bill is passing through the House at the present time, may I ask if the Government will consider the report of the Cave Committee, which recommended that the contributions of employers should be exempt for the purposes of income tax.—Sir A. MOND: Yes, that point will certainly be considered.—Mr. DEVLIN: Will there be a representative on this Commission from Ireland?—Sir A. MOND: No, Sir.

Voluntary Hospitals in Ireland.

Sir MAURICE DOCKRELL asked the Minister of Health if he was aware that Ireland made a very large contribution to the medical and nursing staff of the nation during the war, and that the skill of those serving was to a large extent acquired in the voluntary hospitals of Ireland; if he would explain why Ireland was excluded from the reference to the committee appointed by the late Minister of Health, and was in consequence excluded from the grant of £500,000 about to be made to the voluntary hospitals of the United Kingdom other than those of Ireland; and if Ireland would be granted a sum at least proportioned to her taxation as part of the United Kingdom.—Sir A. MOND replied: I gladly acknowledge the value of the work of the voluntary hospitals of Ireland. I understand that Ireland was excluded from the purview of Lord Cave's Committee as it was thought that the Irish Parliaments might be left free to provide, as they may think fit, for the needs of Irish hospitals. The last part of the question should be addressed to my right hon. friend the Chief Secretary to the Lord Lieutenant.—Sir M. DOCKRELL: Is the right hon. gentleman aware that in Clause 1 of the report of the Cave Committee they evidently contemplate the inclusion of Ireland in the reference and that in Clause 56 they base the recommendation for a grant from the Government upon the fact that the voluntary hospitals of this country did very fine work in treating wounded soldiers? Further, is the right hon. gentleman aware that there was no country which did more in proportion to its resources in this respect than Ireland for wounded soldiers, and will he take steps to prevent gross injustice to Ireland, which will occur if Irish hospitals are excluded from participating in this grant; will the right hon. gentleman kindly give favourable consideration to this matter which involves a great hardship?—Sir A. MOND: As I pointed out in my previous answer, Ireland was not included in the purview of Lord Cave's Committee or in the reference and therefore the grant which I am going to ask the House to give cannot be affected by any question regarding Ireland. Ireland is not within the purview of my department and any further questions on the subject should be addressed to the Chief Secretary for Ireland.—Sir M. DOCKRELL: If Ireland had been included in the reference would the right hon. gentleman feel it his duty to recommend a grant to Ireland?—Mr. DEVLIN: May I ask whether as Ireland pays its proportion to the taxation of the country and as this is a grant to relieve hospitals out of taxation Ireland is not entitled to an equivalent grant for the purpose for which the general sum is intended?—The SPEAKER: The hon. Member should put that question to another Minister.—Mr. DEVLIN: May I then ask the right hon. gentleman whether he will not confer with the Chief Secretary for Ireland and see if the Irish Government cannot do something on behalf of those who are ill in Irish hospitals instead of merely driving more people into these hospitals?—Sir A. MOND: I am not responsible for the health of Ireland and to confer with the Chief Secretary on a matter of Irish business is not within the scope of my duties.

THURSDAY, JUNE 30TH.

Indian Medical Officer's Leave.

Brigadier-General COLVIN asked the Secretary for India whether he was aware that many officers of the Royal Indian Medical Service had had no English leave for many years, and whether having regard to the debilitating climate of India, he would take steps which would enable officers of this Service to have leave at regular periods.—Mr. MONTAGU replied: I regret that owing to the conditions created by the war it has not been possible to grant leave in the Indian Medical Service to the extent desirable. Every effort is being made to bring the Service up to full strength and so make it possible to grant leave more freely. As the hon. and gallant Member is doubtless aware, the terms of service have been immensely improved, with the object of attracting a larger number of candidates of the best type. But the falling-off in the out-turn of the medical schools during the war makes this a slow process. In the meantime all the Government of India can do is to restrict the amount of leave that may be taken by an officer at one time so that as many officers as possible may come home.

Medical Examinations for the Civil Service.

Sir Herbert Nield asked the Secretary to the Treasury whether he was aware that ex-Service men whohave passed the qualifying educational standard for the Civil Service were required to pay a fee of 15s. before they could be medically examined; whether, having regard to the fact that most of these men had been employed temporarily in Government departments at a salary of £3 15s. per week, out of which they had had to pay fees for entering the examination as well as for attending classes, this medical examination fee could be debited to the National Health Insurance Commissioners, seeing that many of these men had never received any pecuniary benefit under the National Health Insurance Act or failing this that only those who had passed the medical examination be asked to refund the money at a later date.—Mr. Hilton Young replied: The fee for medical examination demanded in the cases of candidates for all but the highest appointments in the Civil Service has, after negotiations with the British Medical Association, been fixed at 15s., and I am satisfied that this sum is a reasonable charge for the detailed report required. I am not prepared to impose a charge upon the Exchequer in respect of this fee, for which Health Insurance Funds could in no case be made liable.

Insurance Contributions of Miners.

Mr. Allen Parkinson asked the Minister of Health if any provision had been made to allow for the non-payment of contributions to the National Health Insurance by the miners who had been locked out; if not, was it intended that the workers in the coal industry who had missed 13 weeks' contributions in the present half-year should be mulcted in an arrears fine of 3s. to bring them into full benefit; or would he issue instructions that members were not to be penalised by fine or reduced benefits on account of their contributions not being paid during this period of unemployment.—Sir A. Mond replied: An insured person who has missed 13 contributions in the contribution year ended July 3rd next can, in accordance with the Regulations, avoid any reduction in benefit during the next benefit year by the payment of 3s. (if desired in instalments of 1s.) before the end of next November. In view of the easy conditions of payment and the prospect of regular employment in the mining industry during the intervening months it is not proposed to make any special provision as suggested by the hon. Member.

London Pension Appeal Tribunals.

Lieut.-Colonel Sir Frederick Hall asked the Minister of Pensions whether any and, if so, how many additional appeal tribunals had been set up in the London region since Feb. 28th last; what was now the average number of appeals being heard each week; and what was the usual period which at present elapsed between the date on which an appeal was received by the tribunal and the date on which it was listed for hearing.—Major Barnston (Controller of the Household) replied: There are at present eight Pension Appeal Tribunals sitting in London dealing with approximately 400 cases each week. The average period elapsing between the date a London area appeal is received by the tribunal and the date on which it is listed for hearing is about seven weeks. The number of waiting appeals in this area has been considerably reduced since March last.—Sir F. Hall: Cannot steps be taken to set up additional tribunals in order that this work can be expedited?—Major Barnston: I will communicate that suggestion to my hon. and learned friend.

Voluntary Hospitals in Ireland.

Sir M. Dockrell asked the Chief Secretary for Ireland if he was aware that Ireland made a very large contribution to the medical and nursing staff of the nation during the war, and that the skill of those serving was to a large extent acquired in the voluntary hospitals of Ireland; if he would explain why Ireland was excluded from the reference of the Committee appointed by the late Minister of Health, and was, in consequence, excluded from the grant of £500,000 about to be made to voluntary hospitals of the United Kingdom other than those of Ireland; and if Ireland would be granted a sum at least proportioned to her taxation as part of the United Kingdom.—Sir H. Greenwood replied: I am aware that Ireland made a large contribution to the medical and nursing staff of the nation during the war. The British Government already makes an annual grant of over £16,000 to Irish hospitals. Under present conditions the Government does not see its way clear to ask the House to increase that grant. Lord Cave's Committee did not consider the condition of Irish hospitals on the ground that under the Government of Ireland Act hospitals in Ireland come under the provisions of the two Parliaments.—Sir M. Dockrell: Is it a case of "live horse and you will get grass"? I am sure we have the right hon. gentleman's sympathy, and we ask for its exercise in favour of our hospitals.—Colonel Sir J. Greig: Are there equivalent grants in England or Scotland to hospitals from public funds?—Sir H. Greenwood: I think equivalent grants are not made to hospitals in England or Scotland but exclusively to Ireland. As the hon. gentleman says, I am fully sympathetic, but I regret that from the point of view of Ireland that the people of this country have taken the view, and, indeed, it is the view under the Government of Ireland Act, that matters that come under the two Parliaments of Ireland can no longer be treated by this House especially in face of the financial grants.—Sir. M. Dockrell: Is there to be no contribution until the Irish Parliaments function concurrently? If so we may have to wait indefinitely.—Mr. Devlin: Is it not the fact that one of these Parliaments has postponed its deliberations till September and that the other does not propose to meet at all; and in the meantime while the hospitals are suffering and are in debt because of these political events, are they to be denied the advantages of this grant from the public exchequer to which Ireland pays its fair share? Answer that with all your sympathy.—No further answer was given.

FRIDAY, JULY 1ST.

The Washington Conventions.

Dr. Macnamara (Minister of Labour) moved: "That this House approves the policy of His Majesty's Government respecting the several conventions and recommendations of the International Labour Conference at Washington in November 1919." Speaking of the Maternity Convention (which along with that dealing with the 8-hour day the Government have refused to ratify) the right hon. gentleman said that it was proposed to provide for the six weeks preceding and the six weeks following confinement, and these proposals related only to employed women. Now in this country we had developed over a period of years a system for dealing with this question which was on entirely different lines and which provided not only for employed women but for the wives of employed contributors to the National Health Insurance Scheme—a very much larger number. Our system was animated by the same spirit as this particular Washington Convention, but the Washington Convention if adopted would cut right across the arrangements which during a series of years had been made and built up in this country—and were in advance of those in any other country in the world—under the National Insurance Act and in connexion with maternity and child welfare centres throughout the country. Were they going to scrap their existing machinery built up with a remarkable measure of success as a result of years of effort in order to start again from the beginning on entirely new lines? After full consideration the Government decided that such a change would be unjustifiable.

Mr. G. Barnes appealed to the Government to revive confidence in the Labour Organisation of the League of Nations and to revive confidence in themselves as having signed the Labour Chapter of the Peace Treaty.—Mr. Clynes, speaking for the Labour Party, said that the two questions that still mattered to them were the questions of hours and of maternity conditions. They were asking that women who had to work for their living and enter into employment should be assured of the fullest care and rest many weeks before and after confinement. The nation could not afford to allow women and children to suffer for the sake of a saving of, may be, £2,000,000 a year.—Viscountess Astor urged that the Government should call a conference of women experts to see if any way could be found to deal with this question of maternity.—Mr. A. Chamberlain (Lord Privy Seal), supporting the motion, said this country had really been in the forefront of industrial legislation for the protection of the health of our industrial community. The accomplishment, however, of all their hopes and ideals was not possible so long as some of the greatest nations of the world, and especially some of the greatest industrial nations, took no part in these conferences, were no parties to their decisions, and did not act with us in the general endeavour. In super-legislation of this type the proposals must be made elastic if they were to be successful. He had made inquiries and he was informed that there was nothing comparable to the maternity benefit given in this country in any country in Europe, or, indeed, anywhere with the possible exception of one of our Dominions. If other countries could be persuaded to come up to our standard we would go forward in an endeavour to secure agreement with those countries for still further progress. But it was no use ratifying conventions with one exception in one country, another exception in another country, and a clause in a third which enabled them to accept anything. That way there would be no progress, but a hollow appearance of assent which covered an infinite difference of opinion.

On a division the motion was carried by 164 votes to 53.

Dentists Bill.

On the motion of Sir A. MOND the Lords amendments to the Dentists Bill were agreed to, and the House also agreed to introduce words to prevent the director of a dental company who is not a registered dentist calling himself a registered dentist as far as the company is concerned, while carrying on as a registered dentist during the amalgamation or reconstruction of the company.

MONDAY, JULY 4TH.

Overcrowding in Middlesbrough.

Mr. TREVELYAN THOMSON asked the Minister of Health whether he was aware that considerable sickness and ill-health was being caused in the county borough of Middlesbrough owing to the large amount of overcrowding which existed on account of the shortage of houses, estimated by the local authority as over 2000 houses; and would he therefore reconsider his decision not to sanction the immediate provision of a further 300 houses desired by the local authority.—Sir ALFRED MOND replied: My department has no information confirming the allegation made by the hon. Member. With regard to the latter part of the question, I am afraid I cannot add anything to the reply which I gave to the hon. Member to his question on Wednesday last.

Women in Ministry of Health.

Mr. SWAN asked the Minister of Health how many women in his department or in departments now comprised in the Ministry were receiving a salary of £500 a year in June, 1914; and how many were receiving such a salary now.—Sir ALFRED MOND replied: The number of women employed in 1914 in the departments now comprised in the Ministry of Health who were receiving a salary of £500 a year or over was three. The corresponding number for 1921 is seven.

Pension Appeal Delays.

Lieut.-Colonel HURST asked the Minister of Pensions whether he was aware that the appeal of C. A. Blake, late Royal Engineers, of 2, Priory-street, Greenheys, Manchester, (B D 41, 359) submitted on Dec. 22nd, 1920, was still unheard; whether he would expedite the hearing; whether he was aware of the excessive delay in the hearing of appeals by the appeals tribunals and the hardships thereby caused to appellants; and whether he would take steps to mitigate such hardships by increasing the number of tribunals and by enabling local committees to give grants in aid pending final decisions.—Major TRYON replied: I am informed by the tribunal authorities that this case will be heard during the present week, and that two additional tribunals have recently been set up to deal with appeals arising in the area of the north-western region. With regard to the last part of the question, I would refer my hon. and gallant friend to the answer given to the hon. and gallant Member for Royton on April 21st, of which I am sending him a copy.

Pension Statistics.

Sir WALTER DE FRECE asked the Minister of Pensions the number of applications for pensions which had been rejected; the number of pensions which had been terminated; the number of pensions which had been reduced; and the number of applications for pensions received within the last six months.—Major TRYON replied: During the last six months 59,000 first applications for pensions were made by officers and men, of which 40,700 were accepted and 18,300 were rejected. During the same period 512,500 pensioners were re-examined by medical boards, with the result that in 261,000 cases the pension was continued at the same rate, in 15,500 cases it was increased, in 149,000 it was reduced, and in 51,500 cases the pension was not renewed.

Small-pox and Vaccination.

Mr. ROBERT YOUNG asked the Secretary for Scotland whether any of the infants under five years of age who died of small-pox during the Glasgow outbreak in 1920 had at any time been vaccinated before dying of small-pox.—Mr. MUNRO replied: No child under five years of age who died of small-pox in Glasgow during the outbreak in 1920-21 had been vaccinated at any time.

TUESDAY, JULY 5TH.

National Health Insurance Bill.

On the motion for the third reading of the National Health Insurance Bill,

—Sir GODFREY COLLINS said that according to the report ated to the House by the Minister of Health the total of insured persons was 12,100,000. The intention Bill was to set aside a sum of 1s. 10d. per insured n per annum—a total sum of £2,750,000—for the ost of administration of Approved Societies. In tion a further sum of 6d. was to be set aside for the inistration expenses of the insurance committees, nting in all to £717,000, making a total of over absorbed in administration of the Act of 11. There was also a sum of nearly £600,000 which was uded in the Ministry of Health estimates to be spent in administration, so that nearly £1,000,000 was to be disbursed on administration. He thought that these sums were excessive but he did not suggest that they were unnecessary in the present administration. No one questioned the valuable work being done by Approved Societies and insurance committees throughout the country, but in the interests of insured persons he urged that before these sums were granted the Minister should take steps to curtail the enormous expenditure on the administration of the Act. It had been estimated in a report which had been presented to Parliament that for every £3 paid out in benefit £1 was required for administration expenses. He asked if the time had not come when the whole working of the Act should not be inquired into with a view to its simplification and the reduction of the number of officials employed, so that a large proportion of the contributions might be available for increased benefits.

After some discussion, Sir A. MOND (Minister of Health) said that the Committee which inquired into the cost of the administration of the National Health Insurance Act came to the conclusion that the additional charge of 5d. per head of the insured persons would be a reasonable amount for administration expenses. It would be terrible if it were true, as had been suggested by Sir Godfrey Collins, that for every £3 paid out in benefits £1 was spent in expenses of management. The fact was that those expenses only represented 12½ per cent. of the premiums received. The work of the Insurance Commission and the Approved Societies had been very carefully and conscientiously carried out and the valuations which were now being made were coming out extremely well in almost all districts. He was not sure, however, that the time had not arrived when a searching inquiry into the whole subject by a responsible body might not take place with advantage and he would consider whether such a body should not be set up.

The Bill was read a third time.

Appointments.

BRUCE, J., M.B., C.M. Glasg., D.P.H., has been appointed Medical Officer to the Post Offices of Paisley, Bishopton, and Linwood.

CROOKSHANK, F. G., M.D., F.R.C.P. Lond., Physician to In-patients, the Prince of Wales's General Hospital, N., and the French Hospital, W.C.

WORSTER-DROUGHT, C., M.D. Camb., M.R.C.P. Lond., Assistant Physician to the West End Hospital for Diseases of the Nervous System.

YOW, C. W., M.B. Edin., Senior House Surgeon and Registrar to the Royal Eye Hospital, Southwark.

Manchester Royal Infirmary: HISLOP, G., M.B., B.S. M.B. Syd., House Physicians; HARLEY, H. W., M.B., B.S. Melb., House Surgeon. WILLIAMSON, R., M.B., Ch.B. Vict., and FORD, W. J.

Certifying Surgeons under the Factory and Workshop Acts: FORT, H. M., M.B., Ch.B. Manch. (Oldham West); Lo J., M.B., Ch.B. Aberd. (Oldham East).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Res. Surg. O. £250.
Ayr District Asylum.—Male Asst. P. £400.
Barnsley, Beckett Hospital.—Sen. H.S. £300.
Battersea Borough Council.—Asst. M.O. £550.
Bedford County Hospital.—H.S. £200. Asst. H.S. £150.
Birkenhead Borough Hospital.—Sen. H.S. £250.
Birmingham Education Committee.—Asst. Sch. M.O. £500.
Birmingham General Hospital.—Res. S.O. £180.
Birmingham Queen's Hospital.—Surg. Registrar. £100. As Obstet. and Oph. H.S. £90.
Bolton Infirmary and Dispensary.—Female Third H.S. £175.
Bootle Borough Hospital, Derby-road.—Hon. S. for Diseases of the Throat, Nose, and Ear.
Brighouse Education Committee.—Oculist. £2 2s. per session.
Bristol Royal Hospital for Sick Children and Women.—Hon. S. to Out-patient Department.
British Honduras.—Asst. M.O. $2130.
Bromley Education Committee.—School Dentist. £250.
Brompton Hospital for Consumption and Diseases of the Chest, S.W.—H.P. £50.
Cancer Hospital, Fulham-road, S.W.—H.S. £150.
Cape Hospital Board.—Three Res. Med. O.'s £30 per month.
Carlisle Non-Provident Dispensary.—Res. M.O. £300.
Croydon General Hospital.—Second H.S. £150.
Cumberland Infirmary, Carlisle.—Res. M.O. £180.
Derby, Derbyshire Royal Infirmary.—H.S., H.P. Each £2
Edinburgh Education Authority.—Asst. M.O.'s. £500.
Enfield Education Committee.—Sch. M.O. £500.
Holborn and Finsbury Hospital, Archway Road, N.—Sec Asst. M.O. £300.
Hull Royal Infirmary.—Asst. H.S. £150.
Leeds Public Dispensary.—Sen. Res. M.O. £200.
Leeds University (Leeds Maternity Hospital).—Tutor in Obstetrics and Res. M.O. £300.

Leicester Royal Infirmary.—H.S. £200.
Liverpool, Royal Liverpool Children's Hospital.—Res. H.S. £90.
Llanelly, Borough of.—Female Asst. M.O.H. and Asst. Sch. M.O. £500.
London Temperance Hospital, Hampstead-road, N.W.—Surg. Registrar. 40 guineas. Res. M.O. £200.
Manchester Ancoats Hospital.—H.S. £150.
Metropolitan Borough of Islington.—M.O.H. £1100.
Middlesex Hospital, W.—Cas. M.O. £104.
Miller General Hospital for South-East London.—H.S. £150.
National Hospital for Diseases of the Heart, Westmoreland-street, W.—Pathologist. £250.
Newcastle-upon-Tyne, University of Durham College of Medicine.—Demonstrator of Anatomy. £350.
Newport (Mon.) Royal Gwent Hospital.—H.S. £200.
Nottingham General Hospital.—Res. Cas.O. £250. Also H.S. £200.
Oxford, Radcliffe Infirmary and County Hospital.—Res. Accoucheur. £200. Cas. H.S. £200.
Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Asst. Res. M.O. £60. District Res. M.O. £80.
Reading, Royal Berkshire Hospital.—H.S. £200.
Royal Naval Medical Service.—Surg.-Lieuts. 26*s.* 6*d.* per diem.
St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—H.S. £250.
Salford Royal Hospital.—H.S. £150. Cas. H.S. £150.
Salisbury General Infirmary.—Asst. H.S. £150.
Sheffield University.—Demonstrator in Department of Pathology and Bacteriology.
Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. £150.
South-Eastern Counties of Scotland Joint Sanatorium Board.—Med. Supt. £600.
South London Hospital for Women, Clapham Common, S.W.—H.P. £100. H.S. £100.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. £200.
Wesleyan Missionary Society Women's Auxiliary.—Three Women Doctors.
West London Hospital, Hammersmith-road, W.—P.
Wigan Infirmary.—Jun. H.S. £200.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Pitlochry, at Milngavie, and at Middleton-in-Teesdale (Durham).

Births, Marriages, and Deaths.

BIRTHS.

Hendry.—On June 26th, at Elphinstone-road, Southsea, the wife of Major A. Hendry, R.A.M.C., of a son.

Langrishe.—On July 2nd, at Murdocks House, Ware, the wife of Major John du Pré Langrishe, R.A.M.C., D.S.O., of a daughter.

Lee.—On July 4th, at Gloucester-walk, Kensington, the wife of Robert H. Lee, M.D., of a daughter.

Murphy.—On June 24th, at Linthorpe, Middlesbrough, the wife of Dr. R. W. Murphy, O.B.E., of a daughter.

Smallman.—On the 30th June, at Eastbrook, Park Hill-road, Croydon, the wife of Lieut.-Colonel A. B. Smallman, C.B.E., D.S.O., M.D., of a son.

Warburton.—On July 1st, at *Campden House Court*, Kensington, the wife of P. D. Warburton, M.R.C.S., of a daughter.

Yeoman.—On June 28th, at 10, Duchy-road, Harrogate, to Dr. and Mrs. W. Yeoman—a daughter.

MARRIAGES.

Charlesworth—Bennett.—On June 28th, at St. Mary's Parish Church, Barnes, Henry Charlesworth, C.M.G., Brevet-Colonel, late R.A.M.C., to Constance Katherine, daughter of the late Mr. and Mrs. George Bennett, formerly of Holland Park, and Barnes.

Fry—Miall-Smith.—On July 1st, at the Ethical Church, Bayswater, Hubert John Burgess Fry, B.A., M.D., B.Ch., B.Sc., M.R.C.S., L.R.C.P., D.P.H., to Gladys Miall-Smith, B.Sc., M.B., B.S., M.R.C.S., L.R.C.P., D.P.H.

Malden—Durant.—On June 29th, at St. Andrew's Church, Clewer, Windsor, Edmund Claud Malden, M.A., M.R.C.S., L.R.C.P., to Margaret Dorothy, only daughter of Mr. and Mrs. Durant, of Clewer Court, Windsor.

Piggott—Porter.—On June 21st, at St. Stephen's, Winchmore-hill, F. Stanley L. Piggott, M.R.C.S., to Leslie, second daughter of Mr. S. J. Porter, of Woodside, Winchmore-hill.

Shore—McCallum.—On June 29th, at St. Margaret's Church, Putney Park-lane, Lewis Rudall Shore, M.C., M.A., M.B., Captain, R.A.M.C., to Christina, younger daughter of the late R. A. McCallum, of Putney, and Mrs. McCallum, of Thrale Hall, Streatham.

Tennent—Shearer.—On June 29th, at Strathaven, Robert Tennent, F.R.C.S.E., Park-grove-terrace, Glasgow, W., to Helen Fleming, only daughter of John P. Shearer.

DEATHS.

Dodd.—On June 28th, at Harley-street, W., Henry Work Dodd, F.R.C.S., in his 62nd year.

INDEX TO "THE LANCET," Vol. I., 1921.

The Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, will shortly be published in The Lancet.

Medical Diary.

SOCIETIES.

SOCIETY FOR THE STUDY OF INEBRIETY, at the Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

Tuesday, July 12th.—3.30 p.m., Council Meeting. 4 p.m., Discussion on Alcohol and Alcoholism in Relation to Mental Deficiency, opened by Dr. W. A. Potts.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, July 11th.—12.15 p.m., Dr. Burnford: Pathological Demonstration. 2 p.m., Mr. D. Armour: Operations. 2.30 p.m., Dr. A. Saunders: Visit to Medical Wards. 5 p.m., Lecture:—Mr. D. Buxton: Irregularities of the Teeth.

Tuesday, 10 a.m., Surgical Registrar: Demonstration of Cases. (Surgical Wards.) 12 noon, Mr. T. Gray: Demonstration of Fractures. 2.30 p.m., Mr. Addison: Demonstration of Cases. (Surgical Wards.) 5 p.m., Lecture:—Mr. Addison: Inflammation and Tumours of the Breast.

Wednesday, 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 p.m., Mr. D. Armour: Visit to Surgical Wards. 2 p.m., Mr. Addison: Operations. 5 p.m., Lecture:—Dr. Pritchard: Forms of Arthritis and their Treatment.

Thursday, 10.30 a.m., Dr. Simson: Gynæcological Demonstration. 5 p.m., Special Lecture:—Mr. P. Dunn: Some Points in Relation to Tobacco Amblyopia. (Open to all Medical Practitioners.)

Friday, 10 a.m., Dr. G. Stewart: Neurological Demonstration. 12.15 p.m., Dr. Burnford: Applied Pathology. 2.30 p.m., Mr. Baldwin: Operations. 5 p.m., Lecture:—Dr. Pritchard: Meningitis.

Saturday, 10 a.m., Medical Registrar: Demonstration of Cases. (*Medical Wards.*)

Daily, 10 a.m., Visit of Post-Graduates to Wards. 2 p.m., In-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, July 11th.—10 a.m., Mr. W. E. Tanner: Surgical Out-patients. 2 p.m., Dr. A. J. Whiting: Medical In-patients. 2.30 p.m., Mr. J. B. Banister: *Gynæcological.*

Tuesday.—9.45 a.m., Lt.-Col. R. H. Elliot: Eye Operations and Cases. 2.30 p.m., Dr. J. Metcalfe: X Ray Department. 3 p.m., Lecture Demonstration:—Mr. C. H. Hayton: Anatomy of Ear. Methods of Examination.

Wednesday.—2 p.m., Mr. C. H. Hayton: *Throat Operations.* 2.30 p.m., Dr. W. J. Oliver: Dermatological. 3 p.m., Lecture Demonstration:—Mr. W. E. Tanner: Specimens illustrating Acute Abdominal Emergencies

Thursday.—2 p.m., Mr. N. Fleming: Eye Department. 2.30 p.m., Mr. J. B. Banister: Gynæcological Operations. Dr. J. Metcalfe: Radiology.

Friday.—2 p.m., Dr. C. E. Sundell: Diseases of Children. 4.30 p.m., Lecture Demonstration:—Dr. C. E. Sundell: Bottle Feeding. 5 p.m., Dr. Provis and Mr. Benians: Venereal Department.

Saturday.—10.30 a.m., Mr. W. E. Tanner: Operations. 3 p.m., Mr. H. W. Carson: Surgical In-patients.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, *Post-Graduate Course*, Westmoreland-street, Marylebone, W.

Monday, July 11th.—11.15 a.m., Demonstration (Laboratory and Clinical): Dr. B. T. Parsons-Smith. 2 p.m., Ward Demonstration: Dr. R. O. Moon. 5 p.m., Lecture:—Dr. B. T. Parsons-Smith: Anatomy and Development of the Heart.

Tuesday.—11.15 a.m., Demonstration (Laboratory and Clinical): Dr. J. S. Goodall. 2 p.m., Ward Demonstration: Dr. J. Parkinson. 5 p.m., Lecture:—Sir Sydney Russell-Wells: Diseases of the Aortic Valve.

Wednesday.—11.15 a.m., *Demonstration* (Laboratory and Clinical): Dr. J. S. Goodall. 5 p.m., Lecture:—Dr. F. W. Price: Diseases of the Mitral Valve.

Thursday.—11.15 a.m., Demonstration (Laboratory and Clinical): Dr. R. O. Moon. 2 p.m., Ward Demonstration: *Dr. J. S. Goodall.* 5 p.m., Lecture:—Dr. J. S. Goodall: X Ray in Diagnosis of Cardio-vascular Lesions.

Friday.—11.15 a.m., Demonstration (Laboratory and Clinical): Dr. J. S. Goodall. 2 p.m., Ward Demonstration: Dr. F. W. Price. 5 p.m., Lecture:—Dr. R. O. Moon: *Heart Disease in Children.*

Saturday.—10.30 a.m., Ward Demonstration: Dr. P. Hamill.

Daily (except Saturday):—10 a.m., Sir Sydney Russell-Wells and Dr. J. Parkinson: Instruction in Instrumental Methods of Examination. *Blood Pressure, Polygraph*, Electrocardiograph, and X Ray. 2 p.m., Out-patients. Practical Clinical Demonstrations in the Out-patient Department.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.

Post-Graduate Course on Infant and Child Welfare.

A Course of Twelve Practical *Demonstrations* on the Management and Feeding of Infants and Young Children by Dr. E. Pritchard to Qualified Practitioners.

Tuesday, July 12th.—10.30 a.m., Demonstration IX., The Tuberculous Mother and her Child.

Thursday.—3 p.m., Demonstration X., The Syphilitic Mother and her Child.

Notes, Short Comments, and Answers to Correspondents.

THE WORK OF THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH.[1]

BY DR. H. H. DALE, F.R.S.

I HAVE been asked to speak upon the National Institute for Medical Research, which comprises the Central Research Laboratories under the Medical Research Council. I may remind you that the Medical Research Fund, which the Council administer, was originally established by the National Health Insurance Act, the sum of money annually available being assessed by the number of insured persons. It represented, indeed, a recognition of the fact, long familiar to anyone with knowledge of the position, that treatment directed to the cure or alleviation of existing disease touched only the fringe of the problem; that a relatively small sum spent on facilitating the discovery of causes, and therewith of methods of prevention or of radical treatment, would ultimately save more suffering and do more for national health, than vast sums spent on the application of such remedies as woefully deficient knowledge had yet been able to indicate. The Committee appointed to administer the fund decided that, while the major part should be employed for supporting and promoting medical research in existing institutions—hospital and university laboratories—a substantial sum should be devoted to the formation of a new central institute, staffed by workers who should be in the Committee's whole-time service, and free to receive, from time to time, attached workers from other institutions, whose research could be assisted by the facilities and the opportunities for help and collaboration which such a permanently organised institute could offer.

The History of the Institute.

The first members of the staff of the Institute were appointed in the middle of 1914, and the Committee had used a favourable opportunity to purchase a fine building and grounds at Hampstead, which, after many years' good service as the Mount Vernon Hospital for the treatment of consumption, had been abandoned in favour of more modern premises further from the centre of London. Then came August, 1914, and the whole of the Committee's resources and staff were, for five years, diverted to dealing with the pressing problems created by the absorption of the whole energies of the nation in the successful prosecution of the war. The Hampstead building was immediately handed over to the War Office, and was used as a military hospital by different branches of the services down to the early months of 1919. When at length it was no longer needed in this direction, the task of preparing it for the accommodation of the research staff was taken up again, and by April, 1920, was so far advanced that the members of the staff could take up their work there, and bring into actual being that close coöperation between the different branches of medical research which the Committee had in view in appointing the staff and planning the Institute. Meanwhile, with the absorption of the Health Insurance Commissions into the Ministry of Health, the Medical Research Committee, as a committee under the Insurance scheme, had passed out of existence, but the task which, during the war, they had discharged with such general approbation, was taken up by the newly-constituted Medical Research Council, administering a Treasury grant, and responsible to a Committee of the Privy Council.

The Work in Progress.—Bacteriological Media.

It will be clear, from what I have said that the National Institute for Medical Research at Mount Vernon has only been in existence as a working research institute for a little over a year. The building has been adapted with remarkable ease, and with very little real structural alteration, to provide spacious, airy, and well-lit laboratories. At the same time, in a first year of working in such newly-adapted quarters, a good deal of time has necessarily been spent in plans and preparations. It can cause no surprise, therefore, if I speak more of our organisation, our plans, and our hopes, than of fir[illegible] achievements. The staff, as originally appointed, [illegible] constituted, is organised in four main departments, [illegible] its independent director—the departments of [illegible]gy and experimental pathology, of applied physiology [illegible] hygiene, of biochemistry and pharmacology, and [illegible]al statistics.

[illegible] the new Institute was ready to receive the workers [illegible] constituent departments many of them were still [illegible] in problems arising out of their work during the war. This must be an experience common to many experimental laboratories. Under the stress of war conditions detailed investigation along established lines was largely thrown aside. New methods and new aims were forced upon us. Peace brought the opportunity for more thorough exploration along routes which the hasty survey of war-time had indicated. Let me give you one or two examples. The shortage of the common constituents of bacteriological media led Captain S. R. Douglas, now directing the Bacteriological Department of the Institute to devise, early in the war, a simple method of making such media from natural pancreatic digests of meat or other protein materials—a method which has safely established itself as a valuable aid to all kinds of bacteriological work. The necessity for making certain bacterial vaccines in large quantities, led him to investigate the value for this purpose of bacteria killed, dehydrated, and freed of their oily constituents by extraction with pure acetone. Again he found a method of wide application and usefulness. Possibly a combination of the two kinds of experience led him next to try the effect of the pancreatic ferments on the acetone extracted bacteria. The result is already full of promise, as giving, perhaps, the long-sought method for extracting from many bacteria the poisonous substances which they liberate when they undergo digestion by the ferments of the blood and tissues, and which are responsible for the symptoms constituting what we call the "disease." Hitherto the treatment of disease by antitoxic sera has had its most convincing success against infection by organisms, such as the diphtheria bacillus, which form their soluble poisons even when grown in an artificial broth. Large sums of money have been expended, and the lives of devoted investigators have been sacrificed in unsuccessful attempts to extract from organisms like the typhoid bacillus the toxic substances which they liberate in the body, so as to prepare antitoxins which will neutralise them. In some cases, such as those of the dysentery bacillus and the meningococcus, a fair measure of success has been obtained by injecting suspensions of the organisms themselves into horses and allowing the animals' own body juices to dissolve them and to excite the production of the appropriate antibodies. Captain Douglas's work, growing under the conditions of peace out of his experience during the war, gives hope of a real step forward in the direction of obtaining sera of higher and of definitely measurable value for the treatment of such diseases.

Researches on Tetanus and Silicosis.

Let me quote another example. During the war Dr. W. E. Gye's duties brought him into contact with the danger of tetanus from heavily infected wounds. The organism of tetanus produces an extremely potent toxin in the laboratory, and the antitoxin produced by immunising horses to this was used on a great scale, and undoubtedly saved many lives during the war. But no sufficient explanation was available of certain curious facts concerning the growth of the bacillus and the production of its toxin in the body. A suspension of washed tetanus bacilli or their spores can be injected without harm. If soil is introduced with them they will germinate, flourish, and produce the toxin which causes the disease. With Dr. W. Cramer, of the Imperial Cancer Research Fund, Dr. Gye investigated the soluble constituents of the soil, and found that two common constituents, calcium chloride and hydrated soluble silica, have the property that, when either of them is injected with tetanus spores under the skin of a mouse, it provides the necessary condition for the germination of the spores and the production of the disease. Now this knowledge, which the experimental use of animals alone could have produced, is bound to have a great influence on ideas as to the conditions under which the presence of tetanus organisms in a wound entails the development of tetanus. It is a new step in the direction of eliminating one peculiarly ghastly disease. But it goes much further than that. It directs attention anew to another condition with which the presence of silica has long been associated, though the nature of its action has been obscure. The fact that working in air impregnated with certain kinds of dust leads to injury to the lungs and predisposes to pulmonary consumption has been recognised for centuries. Though the special prevalence of this condition, in workers in materials creating a siliceous dust, has long been known, it is only since Haldane's work in 1902 that the singular position of silica, and the practical harmlessness, or even protective action of other dusts, have been made clear. But though it is now clear that the presence of silica in the lungs leads to fibrosis and predisposes to consumption, and though the vast importance of the matter for the hygiene of many kinds of workers is recognised, and though the possible means of its prevention are being vigorously investigated, such understanding of the condition as could lead to rational measures for its treatment has been wholly wanting. Now comes this evidence that hydrated silica in colloidal solution, can lead to the germination of tetanus spores in the tissues. Already Dr. Gye has applied the knowledge to a study of the mode of action of silicic acid on the tissues and its influence on the growth of other organisms, and already, with Dr. E. H. Kettle, of St. Mary's Hospital, he has been able to show that the tubercle bacillus, which normally in the tissues of the mouse causes at most a localised nodule of infection, when injected with silicic acid causes, in the same species, a spreading infection in the tissues which the silica has injured. Here, then, opens the possibility of a new light on the problem of the consumption which is a scourge of the tin miners, of the gold miners, of the knife grinders, of the ganister-brick makers, of a whole army of workers in indispensable trades; a possibility of new light from an unexpected quarter, shed by knowledge which would be altogether beyond reach without experiments on animals. And surely even a small step towards the solution of a problem of such importance to humanity is worth the sacrifice of a few mice or rabbits.

---

[1] [illegible] address read at the annual general meeting of the [illegible]ch Defence Society on June 29th.

Disseminated Sclerosis.

Another example of work which, also in Dr. Gye's hands, is giving great promise, is the investigation of the disease of the central nervous system known as disseminated or multiple sclerosis. This is a condition regarded as so little susceptible to treatment that but few cases are to be seen in the voluntary hospitals, which must allot their beds to patients for whom there is some hope of remedy. It is to the Poor-law infirmaries that you must go to realise how many are the victims smitten by this mysterious and distressing disease, dragging its course, with alternations of apparent arrest and inevitable progress, through years of misery, for which no fault of the patient or his parents is in any way responsible. The disease has long been recognised and studied by physicians and morbid anatomists, who had arrived at the conclusion that it was "a derangement of the central nervous system due to an inherent defect." Now comes Dr. Gye's evidence that it is due to a definite infection, since the affected nervous matter or the cerebrospinal fluid from a human victim, when injected into rabbits, can transmit the disease, and evoke in them the characteristic lesions of the nervous system. At once we are lifted into an atmosphere of new possibilities. Nobody can investigate the means of preventing, or can suggest rational means of treating "an inherent nervous defect." But here is an infection, with an organism to be discovered, its channel of entry to be identified, its means of access to be removed, the methods for its elimination to be explored. He would be a rash man who would prophecy with confidence, or awaken expectations of early results. But at least there is new hope; there is a line of investigation to pursue. Who, with any knowledge of the vast sum of misery due to this one disease, will dare to lift a finger or speak a word which can hinder?

Other Branches of Work.

I should keep you much too long if I were to try to indicate to you merely the lines of work on which all the different workers in the Institute have embarked. Much of it, such as Dr. Leonard Hill's work on the conditions of ventilation and surface cooling needed for health and vigour, hardly needs at the moment experiments on animals of the kind which your Society is chiefly concerned to defend from ignorant attacks and misrepresentation. His usual experimental animals are himself, his colleagues, and volunteers from the Institute's personnel. Dr. John Brownlee, in his statistical department, takes his material chiefly from the large scale experiments which our ignorance allows Nature still to make on our fellow men. Mr. Barnard's investigation of the minute structure of micro-organisms, by means of his most recent developments of microscopic and photographic technique; Mr. Clifford Dobell's critical survey of the protozoological examinations made on the excreta of people in this country, showing the unsuspected presence of the amœba of tropical dysentery in a material percentage of us healthy Englishmen; these depend hardly at all on the use of animals for experiment at the moment. But the whole significance and value of all their work depend on the knowledge which we could not have obtained except by the directly experimental method.

There are many other items of our activity I could describe: Dr. Leonard Colebrook's work on actinomycosis, work by others of us on shock in wounded men, and on the significance of the capillary circulation in connexion therewith, work on anaphylaxis, on the reaction of blood in the body, and so forth. But there is only one other side of our work which I can mention with any detail. A very important task on which some members of our staff have been engaged has been the control of the activity and freedom from dangerous toxicity of some of the modern potent remedies, such as salvarsan and its analogues, which cannot by any known chemical test be guaranteed as invariably safe for use in human theuraputics. I need not say that such remedies were discovered by means of experiment on animals; but I am not sure whether it is generally realised that there is a large and growing class of them which could not be used at all, with any confidence in their efficacy and in their safety for the patient, if their quality were not subjected, regularly and systematically, to the test of experiment on animals. I venture to say that it is hardly creditable to this country that we have hitherto had no publicly established organisation for the control of such remedies; but, to the limited extent to which the present state of our law and the willing coöperation of British manufacturers make it possible, such control is already being exercised by a department of the National Institute.

I could spend much longer telling you of our plans, but I have said enough to enable you to realise how sincerely, with all workers in medical science, we must appreciate the efforts of this Society to help us, by developing a sane and informed public opinion. Genuine, well-informed criticism we shall always welcome; indeed, as an Institute supported out of public funds, it is peculiarly our duty to have to regard it. On the other hand, we should be false to our trust if we spent the time, which the Government pays us to give to research, in controversy with ignorance which no truth will convince. We realise the immense service to science which this Society is doing in making the real facts of the situation available to all who sincerely desire to know them.

PUBLIC HEALTH IN EGYPT, 1919.[1]

THE population of Egypt in 1919 is calculated to have been 12,878,000, as compared with 12,905,500 in 1918; on this basis the birth-rate was 38 and the death-rate 30 per 1000, as compared with 39 and 40 respectively per 1000 in 1918. Disregarding the exceptional cases of Ismailia (with a birth-rate of 160 and a death-rate of 211), and the Sinai province (with corresponding ratios of 78 and 113), the births ranged from 28 per 1000 in Aswân province to 44 in Port Said, Damietta, and Asyut; and the deaths from 25 in Damietta and Beni Suef to 41 in Alexandria and 42 in Cairo. In the case of each of these two large cities the deaths exceeded the births, which were 35 and 40 per 1000 respectively. Colonel Cathcart Garner, Director-General of the Department of Public Health, states that it was found that the formidable increase in cost of articles of food was having a very deleterious effect on the health of the population, especially of the poorer classes; and that energetic measures were taken, especially as regards the sale of flour at reasonable prices, by which a great improvement was brought about. This is a point that should be noted by the advocates of a policy of "self-determination" in countries, such as Egypt and India, where it is the strength and justice of British rule that constitutes a guarantee against oppression of the poorest and most helpless classes of the population. Much improvement has been effected in the methods of dealing with "unhealthy, inconvenient, and dangerous establishments"; model conditions for fifty different types of such (chiefly connected with the manufacture, storage, or sale of articles of food or drink) were laid down and published; all such licensed establishments were registered, and special inspectors appointed to ensure that the regulations were carried out. It is, however, admitted that these new conditions cannot be applied to existing establishments, in many cases, without practically pulling down the old building and reconstructing it anew; such a drastic procedure is not carried out, but improvements are effected, as far as possible, with the consent and goodwill of the proprietors.

There are 21 general hospitals in Egypt, providing 4502 beds, and the in-patients numbered 61,704, compared with 75,002 in 1918. The reduction was partly due to the disturbed state of the country in March, April, and May, and partly to the cessation of the epidemic of influenza. There is, however, an increased disposition on the part of the population to avail themselves of hospital treatment, and increase of accommodation is required in many places. There were also 219,573 new out-patients treated. The cost of maintenance was 183,142 livres Egyptiennes (one L.E. = 20s. 3¾d.), being an increase of L.E. 16,923 on that of the previous year, due to the high prices of food, drugs, &c.; the cost of building repairs and of the central administration is not included in this sum. The expenditure per bed per annum was L.E. 39.883, and per patient per day 170 milliemes (about 45 pence), as compared with 130 milliemes (32½ pence) in 1916. Since the commencement of the war there has been a total of 45,172 military patients (including prisoners of war) admitted to various hospitals throughout the country; 23,014 were discharged fit for duty, and 1307 died, the remainder being sent to convalescent camps, transferred to other hospitals, or discharged to England. During 1919 the total hospital in-patients treated throughout Egypt numbered 61,704, the most prevalent affections being venereal disease (9811), traumatic injuries (3929), dysentery, diarrhœa and enteritis (1670), and fractures (1544). There were 770 cases of ankylostomiasis, but only 667 of malaria.

THE WOOD-HILL FUND.

THE following subscriptions and promises have been received to the fund for reimbursing Dr. H. Wood-Hill in the very heavy expenses incurred by him in the case Clayden v. Wood-Hill, in addition to those recorded in the lists published in our issues of Dec. 3rd (p. 1187) and Dec. 17th (p. 1299). There is still ample need for further support.

Births, Marriages, and Deaths.

BIRTHS.

FOLEY.—On Dec. 17th, at Ebury-street, the wife of Walter B. Foley, M.B., of a daughter.

LOVEDAY.—On Dec. 18th, at Spring Lodge, Fallowfield, Manchester, the wife of Dr. G. E. Loveday, of a son.

MARRIAGES.

WARDROP—SUTTON.—On Dec. 17th, at St. Anne's Church, Highgate, J. G. Wardrop, M.D., Leamington, eldest son of John G. Wardrop, Lynthorpe, Montpelier-road, Ealing, to Muriel, daughter of A. Sutton, 9, Brookfield Park, N.W.

DEATHS.

DOBRASHIAN.—On Dec. 21st, at 32, Greenhill-road, Harlesden, N.W., Gabriel S. Dobrashian, M.R.C.S. Eng., L.S.A., aged 67 years.

LITTLEWOOD.—On Dec. 18th, suddenly, at Erpingham Lodge, Norfolk, Harry Littlewood, C.M.G., F.R.C.S.Eng., in his 61st year.

OATES.—On Dec. 21st, at Langside-avenue, Putney, S.W., Robert Oates, M.B., L.R.C.S., in his 95th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

A NUMBER of provincial schools are reported to have been in the midst of an epidemic of influenza when they broke up for the Christmas holidays.

otes, Sho rt Comments, and Answers to Correspondents.

THE PERILS OF THE WEEK-END—AND AFTER.

In the normal healthy organism, apart from mere greediness, appetite is determined by the speed of basal metabolism, and, whatever physiological text-books say to the contrary, it is a matter of ordinary human experience that this metabolism can be greatly speeded up. The wider freedom of the leisure hours of the week-end produces in the case of many ordinarily sedentary people a condition of well-being and increased appetite which is apt to last on into the beginning of the working week with disastrous consequences; for, with the return to the warmth, shelter, and restricted elbow-room of the office, the means for getting rid of waste products of metabolism are at once reduced and a heavy price is paid for dietary indiscretion which would have been tolerated with impunity on the preceding days. Many people found the uncongenial restrictions associated with food rationing resulted in a diminution of digestive disturbances to which they had accustomed themselves as part of the inevitable routine of city life. It is easier to bear good-humouredly a compulsory rationing in which one's friends and neighbours share than personally to initiate voluntary restriction in the presence of plenty. But there is little doubt that it would greatly add to the amenities of office life and to the digestive comfort and mental efficiency of its denizens, should it become the usual practice of returned week-enders to drop their midday meal on Monday. Should this prove too high a task, other means might be taken to get rid of incomplete products of combustion arising from the excessive use of fuel in an engine which has slowed down. But restricted intake would be better.

HEALTH IN A FEW WORDS.

Sir Robert H. Firth, author of well-known text-books on hygiene and joint author with Colonel J. Lane Notter of *Practical Domestic Hygiene*, has compiled a useful 14-page folder which does not belie its title, Health in a Few Words. Intended for the use of anyone interested in domestic hygiene—and everyone should be—it is especially suitable for distribution by medical officers of health among their health officials, the published price, 2*d*., bringing it within the reach of all. The folder contains notes on the dwelling and its proper sanitary care, the physics of air and its effects upon health, water in the economy of the body, food, personal hygiene, the care of the child, and such matters as require to be known with regard to infection and disinfection, salient facts being printed in red. A table is given showing the value in calories per ounce of the more common articles of diet, and under the heading of infection are conveniently set out in tabular form the periods of incubation, onset, and disappearance of eruption, period of quarantine, and cessation of the contagious period of infectious diseases. If every man and woman in the community could be induced to digest and apply the information contained in this folder it would conduce to a healthier and more efficient population. Messrs. John Bale, Sons and Danielsson, Ltd., of 83-91, Great Titchfield-street, London, W., are the publishers.

SWIMMING-BATH SANITATION.

A comprehensive article by Mr. G. M. Fair in the current number of the *International Journal of Public Health* recalls the hygienic importance of aiming at a high standard of cleanliness for bathers themselves and the water in which they bathe. Among diseases which may be transmitted by bathing in public baths, he places infections of the intestinal tract, respiratory system, skin, eye and ear, and venereal disease. To the frequency of middle-ear affections recent correspondence in our columns has borne witness. As regards the mode of spread of disease, various possibilities are considered by Mr. Fair, including water-supply from an impure source and contamination by bathers, and the common use of infected towels and bathing suits which have been imperfectly sterilised. The lack of proper adjustment of the temperature of the water and room air and inadequate ventilation are also recognised as likely to lead to harmful results. The regulations in force in parts of U.S.A. to ensure the purity of the swimming bath are quoted by him as examples of sanitary administration which might well be universally adopted in the interests of the public. They concern the design and maintenance of the bath, the dressing-rooms, shower-baths, galleries, and enclosing structure, as well as the supervision of the bathers, their costumes, and towels. The requisite degree of purity of the water can be secured either by the periodic change or by the continuous flow system, or the re-purification process of circulation by pumping the used water through filters and returning it to the bath. As an alternative, disinfection of the water is advocated either by chlorination or by copper sulphate, or by exposure of the re-circulated supply to the action of ultra-violet light, chlorine, or ozone. It is clear that the hygienic condition of the bath will also depend on its size, the number of bathers, their state of cleanliness, as well as the amount of fresh or disinfected water added.

For the bath supply water bacteriological standards of purity, as proposed by the public health authorities, have been decreed in certain of the American States, varying between the total bacterial counts per c.cm. of 500 to 1000 organisms developing on agar incubated at 37° C. for 48 hours. For *B. coli* there should be a proportion not higher than 25 per cent. of this total. Other authorities aim at only one to 10 of *B. coli* per c.cm. and some even at an ideal standard conforming with drinking water, which permits a total count of 100 colonies and a *B. coli* content of one in 50 c.cm. The difficulties of formulating and adhering to such standards are recognised, but it is maintained that they can be met by properly organised control and supervision. In addition to governing the construction, equipment, and operation of the baths, the regulations conforming with the desired standards ensure sanitary control of the premises, the cleansing and emptying of the baths, and the correct disposal of the water on discharge. They further provide for the supply of sterilised towels and bathing suits and instruct bathers to cleanse themselves thoroughly with soap and water douche before entering the bath. Other important details, such as the supply of spittoons, the inspection of disease suspects, and the prohibition of smoking, are included in a code which, if carried out, should attain a standard of swimming-bath hygiene and sanitation approaching perfection. The only reservation in our mind is whether, in view of the formidable regulations, a prospective bather may not consider a fresh-water bath in an enclosure—never so enjoyable as a dip in the open sea—to be hardly worth the bother or the risk where the necessary precautions are not in force.

SAFEGUARDING OF INDUSTRIES ACT: EXCLUSION OF SANTONIN.

The Board of Trade announced on Dec. 21st that the referee, after hearing a complaint under Section 1 (5) that santonin had been improperly included in the lists of articles chargeable with duty under Part I. of the Act, had given a judgment upholding the complaint. Accordingly santonin is withdrawn from the lists as from Dec. 20th.

FLOWER HOUSE, CATFORD.

This well-known house of retreat for the reception of male patients suffering from mental and nervous disorders was visited recently by a representative of The Lancet in view of developments which are projected by the management of the institution. The house, which is just within the boundaries of the County of London, is an old family mansion standing in grounds of 22 acres comprising a large playing field, the cricket field being "as large as Lord's," tennis courts, football grounds, ornamental and vegetable gardens. The whole estate is well timbered, while the neighbouring park lands are exceptionally fine, making the environment beautiful. The house itself is well appointed and furnished, is licensed for 32 patients, and the voluntary boarder is especially catered for, all possibilities of freedom being accorded. A scheme is in progress for the reception of female patients. This will entail a good deal of outlay for extension, but there is no doubt that well found and managed retreats for female patients of this sort are required.

TAXATION FOR HOSPITAL UPKEEP.

The city of Whittier, California, established as a Quaker settlement 35 years ago, and now a flourishing community of 10,000 inhabitants, was in April, 1921, presented with a hospital, the gift of a neighbouring landowner. The latter philanthropist was prepared also to equip the hospital, but the municipal authorities decided to give the city the opportunity of sharing the task of this provision, and by invitation of the chamber of commerce the various churches, lodges, and clubs joined energetically in the work. The Woman's City Club of Whittier, for instance, became responsible for the maternity department, whilst the members of the medical profession equipped an operating room with the most modern apparatus. A fund of $25,000 was raised among the citizens for purposes of maintenance. Finally, in September, the California Legislature enacted a law authorising cities of the fourth and fifth classes to accept gifts from individuals for the establishment of hospitals, and empowering them to levy any necessary taxation for maintenance, upkeep, and extension of such hospitals.

The above information is derived from the *Bulletin* of the Chicago School of Sanitary Instruction, which makes the editorial comment that the action of the Whittier municipal authorities should be of value to smaller towns and cities throughout the U.S.A. in suggesting to them the way by which adequate hospital facilities may be obtained.

The training of native midwives has been continued, though the seven training centres had to be closed for various periods on account of the disturbances in March; 59 *dayas* were trained, a better type of pupil is being secured, and a considerable amount of public interest is now being taken in the matter. Another most important work is that of the ophthalmic hospitals, of which 18 have been established since Sir E. Cassel made his gift of 40.000 livres Egyptiennes in 1903: 11 hospitals have been built and equipped at a cost of L.E. 65,000, mainly raised by subscriptions among the Egyptians themselves. There are five travelling camp hospitals, of which it is stated that it is owing to the reputation gained by them that Egypt has learned to value the means of ophthalmic relief, and to obtain it by building permanent hospitals. More than 12,000 patients (15 per cent. of the new cases) during 1919 were blind in one or both eyes. A system of prophylaxis has yet to be discovered, but the clinical research work which is being carried out should eventually shed some light on prophylactic measures. The importance of treatment in young children is beginning to be recognised by the people, more than 6 per cent. of the cases were infants less than a year old, and 39 per cent. were under 15 years of age. All the provinces, except two, now have an ophthalmic hospital. Colonel Garner states that it is impossible to cope with the ophthalmic work in Cairo with the existing facilities, and that a new hospital with 100 beds, and able to treat 2000 cases daily in the summer, is urgently required.

In regard to infectious diseases generally, there was less typhus than in the four preceding years, but the death-rate (32·8 per cent.) among the 16,970 cases was higher than in any year since 1912: a similar observation applies to relapsing fever (3272 cases and 598 deaths). Small-pox was much more prevalent (7805 cases, of which 24·39 per cent. were fatal) than in any of the preceding nine years; the number of cases reported was probably much below those that actually occurred, but was still much higher than in any year of the decennium, 1910–19. Malaria was prevalent in the province of Aswân (1304 cases), especially in the district of Derr, where Abu Simbel (so well known to travellers on account of its gigantic statues) had a mortality in November at the rate of 400 per 1000 per annum. Anti-mosquito measures were taken immediately, and a passenger control station established at Shellal, just above Aswân. Influenza was made compulsorily notifiable in February, 2106 cases being recorded, and practically disappeared during that month. There were 877 "declared cases" of plague, of which 737 were of the bubonic type; 224 cases, with 112 deaths, occurred in the district of Mallawi in Asyut province, and 126 cases with 76 deaths in the governorate of Suez. Throughout Egypt as a whole, 59·4 per cent. of the deaths occurred in April, May and June. A very great increase in the output of vaccine lymph is recorded, 5,645,020 doses having been issued, compared with 1,428,500 in 1918; the quality, however, was kept up to a high standard, 81·8 of the samples tested producing four pustules. Of 860 persons fully treated at the Anti-rabic Institute only five died (0·58 per cent.); 15 others died either during treatment or less than 15 days after its completion, giving an additional mortality of 1·74 per cent. An increase of activity in many other spheres of public health work throughout the country is recorded in this interesting report. A map showing the existing administrative divisions of the country, such as are attached to the reports of most of the Indian and Colonial Governments, would be an acceptable addition.

HOUSING IN YORKSHIRE AND LANCASHIRE.

Overcrowding in Yorkshire.—At the Yorkshire Housing and Town Planning Conference held in Leeds on July 1st, the Chairman, Mr. E. Hawksworth, said that if they set about educating the working classes to the knowledge that it would be to the advantage of both themselves and their cities to live in a better type of house, it would be a very useful service. It was not always the poorest who lived in the worst house. The Conference passed the following resolution:—

> "That this Conference is emphatically of opinion that to enable the declared policy of the Ministry of Health concerning the deflation of prices in building tenders to be carried into effect, with the goodwill and full approval of local authorities in Yorkshire, the Minister of Health will be wise in recognising that wasteful and uneconomic results will inevitably follow if the financial officers of the Ministry continue to insist that schemes must be completed by July, 1922."

I[illegible] stated by one speaker that in the village of Grime-[illegible] ad come across three houses, each with two bed-[illegible] two downstairs rooms, in each of which there [illegible]s than 27 people living. Such a condition of [illegible] a standing disgrace to the country.

[illegible]ng in *Manchester.*—At a meeting of the Lancashire [illegible]ire Housing Council held in Manchester on June 28th [illegible]rman of the Manchester Housing Committee [illegible] that for the needs of the nation 800,000 houses were [illegible], but little progress had been made. At the end of the war 17,000 new houses were required to meet the actual shortage in Manchester alone, and if the slums were cleared away, 50,000 houses would be needed. Up to now 300 houses had been finished; work had been started on 2000, and it was calculated that by November next year—four years after the armistice—perhaps 2500 houses would be completed. To meet the annual increase of population in Manchester alone, 1500 new houses were needed—i.e., between 1918—22, 6000 were required and only 2500 would be available for the increased population during the four years. With the 17,000 required at the end of the war 23,000 houses should have been built. In the district of Didsbury, on the outskirts of the city, it was found that in three streets so great was the overcrowding that 20 per cent. of the houses had not enough rooms to allow separation of the sexes. Girls and boys between the ages of 10 and 18 years were sleeping in the same bedrooms. A resolution was passed calling upon the Government and Members of Parliament to fulfil the pledges given in 1918 relative to a National Housing Scheme. There are upwards of 10,000 people on the waiting lists in Manchester who are prepared to pay the rents demanded by the Ministry of Health.

Overcrowding in the South and West.—That the above information is typical of the state of affairs throughout the country is made evident by the annual reports of the medical officers of health for Norwich, Colchester, Torquay, Hove, Margate, Southwark, and Stoke Newington, in each of which mention is made of serious housing shortage and consequent overcrowding.

RUBBER RINGS ROUND TEST-TUBES.

A SUGGESTION especially useful for anyone who has to do minor chemical investigations in inconvenient surroundings is made in the *Chemical News* (July 1st, p. 7) by "W. K. F." Rubber rings, as he says, are obtainable in all sizes and the placing of a ring about ⅜ inch in diameter round a test-tube about 1 inch from the mouth has many advantages. The ring enables a test-tube to be supported between two nails driven into the edge of a shelf, and, moreover, enables it to be laid on a bench when not too full without spilling the contents, besides saving the fingers when the tube is held over a burner. "W. K. F." claims also that the ringed tube is less liable to be broken. Though the trained chemist in a well-equipped laboratory may find little use for this simple expedient, we can imagine its adoption by medical men to save the space of a test-tube stand.

THE WOMEN'S HOLIDAY FUND.

AN appeal is made for assistance to carry on the excellent work of the Women's Holiday Fund, a work rendered more than ever necessary this year by the distress arising through unemployment. In a period of economic stress the working woman is generally the first to suffer; her sacrifices for husband and children soon deprive her of the necessaries of life, and certainly of such a luxury as a holiday. More help is needed if many of these tired women are to obtain a rest in the country or at the seaside; they themselves can contribute but little towards the necessary expenses, and it is hoped that there will be a very generous response to the appeal from all to whom the thought of passing a year without such a change is inconceivable. The society has just opened, at St. Leonards-on-Sea, a small Home of its own, with a trained matron in charge, where good food and rest are available for a few London women and their babies. The full cost of a fortnight's holiday for a mother and baby, including railway fare, is £3 10*s*. Ten guineas will provide a holiday for three mothers and babies. Contributions, large and small, towards the upkeep of the Home and also for the general work of the Fund, are urgently needed, and should be sent to the Secretary, Women's Holiday Fund, 76, Denison House, 296, Vauxhall Bridge-road, S.W. 1.

L.R.C.S.I., L.S.A.—Our correspondent has decided on the best suburban locality in the circumstances which he mentions.

A CASE OF PERSISTENT DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Will any professional brother give me a help if he can? I am 75 and have travelled a good deal in the tropics, &c., but have had no disease from that. Now for a few years I have had persistent diarrhœa; no hæmorrhage, mucus, or pain; no albumin or sugar. I have seen specialists and been under treatment for three years. I have in all lost 4 st., and to-day I still have this persistent diarrhœa, which is weakening me, and nothing I can find to arrest. Will someone advise and give a prescription?

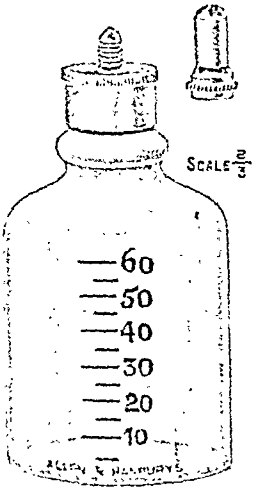
I am, Sir, yours faithfully,

Dec. 23rd, 1921. SURGEON.

A VALUABLE MEDICAL LIBRARY.

SEVENTY-SEVEN years have elapsed since the foundation of the firm now known as H. K. Lewis and Co., Ltd., of 136, Gower-street. The directors of the business have issued an illustrated brochure containing a brief account of its history and development from 1844 till the present day. The exact year when the well-known circulating library was opened is not certain, but must have been 1846, 1847, or 1848; it was established to meet the needs of professional men with regard to current medical literature, and enables subscribers to keep abreast of recent work of all kinds. A library reading and writing room is provided for the use of subscribers, and all books are arranged so that they may be freely inspected and exchanged. The catalogue, revised to December, 1917, with a supplement for 1918–1920, contains upwards of 13,000 titles, with a classified index of authors and subjects.

AN IMPROVED CHLOROFORM BOTTLE.



Mr. E. S. Ellis, M.R.C.S., honorary anæsthetist to the Hospital for Sick Children, Gloucester, calls our attention to an improvement which he has made in Mills's chloroform bottle. To prevent the falling out of the leaden stopper, an accident which may happen with disastrous result, he has had made by Messrs. Allen and Hanburys a bottle in which the stopper screws, not to a collar, which is also liable to come off, but to a thread cast in the glass itself. A second feature of the bottle is that its squat shape makes it more stable, while the graduation in cubic centimetres or ounces, reading from below upwards, simplifies the administration of mixtures.

RELATIVE VALUE OF INSULATING SUBSTANCES.

THE recently issued special report[1] on Heat Insulators by the Engineering Committee of the Food Investigation Board deals with the thermal conductivity of material usually employed in cold storage work. The experiments carried out in order to determine relative values in this respect were directed by Mr. Ezer Griffiths, D.Sc., a member of the committee. In the course of the work it was established that for most substances, *in order to maintain* a vertical wall lagged with a substance at a uniform temperature from top to bottom, it is necessary to supply more heat per unit area to the bottom than to the top of the wall. This necessity was traced to loss of heat due to convection currents set up in the air circulating through the pores of the insulating material, and much of the apparent change of conductivity with temperature was traced to these currents.

Cork, slagwood, charcoal, and wood fibres, when of good quality and dry, were found to have practically the same thermal conductivity—viz., 0·00011 g. cal. per sec. per cm. per 1° C. [= 0·32 British thermal units per sq. ft. per hour for 1" and for 1° F. diff.]; from the fact that entirely different materials were found about equally good as insulators it appeared that their resistance to conduction is not far from the limiting value that is *practically obtainable* by dividing the air space. Still air has a thermal conductivity of only 0·00005 C.G.S. units [= 14 B.T.U.'s per sq. ft. per hour for 1" and for 1° F. diff.] or barely half that of the best of these materials, so that there is still a margin for improvement by finding a more suitable material in cellular form.

It is definitely stated in the report that although different brands of cork vary slightly in their efficiency as insulators, with good brands such differences are not very considerable, and that the extravagant claims made for certain insulating materials are devoid of foundation.

A WARNING.

WE are informed that a man, posing as a naval officer and a nephew of Prof. Thelwall Thomas, of Liverpool, is calling on doctors in the London area who have been either students or house surgeons in Liverpool. He endeavours to obtain hospitality and money. Prof. Thelwall Thomas informs us that he is an impostor.

THE THERAPEUTIC VALUE OF ALCOHOL.

IN the *Journal* of the American Medical Association of Dec. 3rd, 1921, an attempt is made to secure the views of a representative number of the medical profession in America upon the use of alcohol as a therapeutic agent. The profession is quoted on both sides in the controversy upon this subject, and in order to obtain an accurate division of opinion with regard to the latter a questionnaire has been carefully prepared and sent to 40,000 physicians—every other name on the mailing list of the *Journal*—and to 10,000 physicians who are neither members of the Association nor subscribers to the *Journal*. The terms of the questions asked are briefly as follows:—

Questionnaire on Alcohol as a Therapeutic Agent.

In what line of practice are you engaged? General practice? Specialty?

Do you regard whisky, beer, or wine, as necessary therapeutic agents in the practice of medicine?

[By "whisky" is meant distilled liquors, whether whisky, brandy, gin, or rum. By "beer" is meant beer with the same alcoholic content as prevailed before prohibition went into effect, also ale, stout, porter, &c.]

Have instances occurred in your own practice in which unnecessary suffering or death has resulted from the enforcement of prohibition laws?

How many times have you found it *advisable to prescribe* these liquors in a month?

Is the prescribing of alcoholic liquors forbidden by your State law?

The present regulations limit the number of prescriptions to 100 in three months. In your opinion, should there be any limit to the number of prescriptions for alcoholic liquors a physician may write?

In your opinion, should physicians be restricted in prescribing whisky, beer, and wine?

The list of names covers the whole country, and much interest will attach to the replies given in answer to this referendum.

INCREASE OF PENSIONS SINCE 1914.

THE following interesting table appears as an appendix to Mr. Wilkinson Sherren's exhaustive "Rights of the Ex-Service Man and Woman," a complete guide to war disablement pensions, allowances, grants, gratuities, rights of appeal, provisions for treatment and training, land settlement and overseas settlement, &c., to which the Right Hon. C. A. McCurdy, M.P., contributes a preface. The book is published by L. J. Gooding, 25, Old Queen-street, Westminster, at the price of 6*d*.

CLASS.	AMOUNT PAYABLE.		
	In 1914.	In September, 1918.	Present day.
Privates — Total disablement.	10/6 to 17/6	27/6 with children's allowances.	40/– with children's allowances.
Wife of totally disabled man.	Nothing	Nothing.	10/– a week.
Childless widow.	5/–	13/9 rising to 15/– at 45.	Under 40, 20/– Over 40, 26/8.
Widow with one child.	6/6	20/5 with 1/3 extra at 45.	36/8
Widow with three children.	9/6	29/7 with 1/3 extra at 45.	50/2
Motherless children.	3/– each	10/– for first, 9/2 for each other child.	12/– for first and 11/– for each other child.
Pending settlement of pension claim.	Nothing	27/6 with allowances for wife and children.	*40/– with allowances for wife and children.

* In the case of men discharged before Oct. 1st, 1921, or in the case of men who were in hospital on Sept. 30th, 1921, and were invalided without returning to duty.

S.M.S. MEDICA
LIBRARY,
JAIPUR

been caused, however much it may have been aggravated, by the individual experiences. In the armies of the Allies and those of the enemy millions of men were exposed to similar conditions, yet only a small number were brought to our hospitals suffering from a neurosis. Doubtless all of us who were in the line showed for a longer or shorter period the disturbances due to fatigue or functional hypertrophy of certain nervous mechanisms, but only those succumbed who were organically unsound. Sir Frederick Mott was able to obtain a history of pre-existing neurotic symptoms in 80 per cent. of the cases of soldiers under his care for neurotic disorders. But the point hardly needs pressing; had those who have contributed to the literature of the war neuroses been permitted to undertake regimental duty in the line, thus to know their men, as one only can do by constant contact, they would have found little difficulty in spotting the future cases of neurosis before ever a shot was fired. Were these cases of organic nervous weakness the victims of infantile and childhood experiences that left an indelible mark on their nervous constitution? There is no reason to suppose that as a whole their experiences differed from those of the average child of their particular social milieu. We are, I think, justified in assuming that an organic disability exists as an antecedent to every neurosis, and in employing methods for objective evaluation of organic efficiency in looking for it.

STUDY OF CONDUCT AND OF SPECIFIC REACTION OR MOVEMENT.

Such an objective study must necessarily be conducted along many lines of observation; but, broadly speaking, there are two methods at our disposal—the study of conduct and the study of specific bodily reactions or movements.

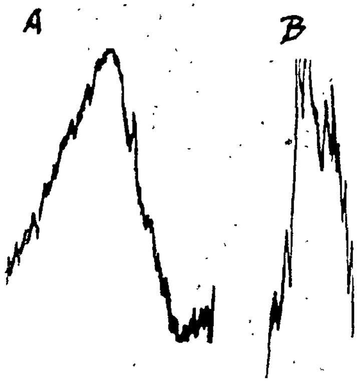
The study of conduct is a purely objective study of all those activities which collectively represent to us all that we can know by observation of the exterior aspect of life. The study of movements is supplementary to the study of conduct. By movement we understand not only the manifest muscular reactions, but also secretory and circulatory responses. The study of conduct in a search for signs pointing to definite organic disorders must of necessity furnish much evidence that is ambiguous and much that is definitely misleading. The recognition of the actuality of our own and our fellow men's life of unique and incommunicable feeling compels us to admit the existence of much that from its incommunicable nature falls outside the sphere of physical reality. The weakness of any objective study of conduct is that much of our information depends on verbal communications from the subject studied.

Now, quite apart from this unique incommunicable aspect of experience, there are a host of affective states and sensory experiences that we have to a great extent in common and that we find the greatest difficulty in communicating. Language is in its essence a method of communication evolved solely in response to practical needs—that is, for the communication of information essential to the maintenance of our social life. The communication of the greater part of our experience serves no such useful purpose, and hence has never acted as a stimulus for the evolution of appropriate language. Those of us who are musicians know that we have a whole range of experience which in its broader aspects we have no reason to suppose to be unique, but which for all that remains practically incommunicable. It is the function of the artist to bridge this gap in our social life by presenting his immediate intuition of reality, but we all know how rarely and how imperfectly art succeeds. It [illegible]ly for this reason that the study of those [illegible] which are the exterior signs of states of [illegible]mes so important. When our methods [illegible]on become sufficiently perfected we may [illegible] check by means of these stereotyped forms [illegible] the deductions that we draw from the actions, words, and silences of our patients.

TYPES OF MOVEMENT STUDIED.

The movements which I propose to study are of two types—those which are the exterior manifestations of the specialised response of certain nervous mechanisms, and those which connote the generalised reaction of the body as a whole to stimuli which disturb or threaten the unity of vital action. With movements of the first type we may deal briefly, because their disturbances belong rather to the category of what are known as organic nervous diseases than to that of the neuroses. When we speak and at the same time press the hand on the throat we become aware of movements of the larynx which are easily palpable. They are still more pronounced when we sing, and by pressing the nail of the index finger on the free edge of the upper border of the thyroid cartilage we may readily feel the cartilage move upwards higher and higher with each ascending note of an octave and descend by similar steps as we go down the scale. These movements may be recorded if we fix to the neck a firm leather collar supporting a small spring, one end of which presses downwards on the cartilage and the other is fixed to the collar. At right angles from the spring a small button is soldered which impinges on the drum of an air capsule conveniently attached to the collar. The vibrations of the tambour membrane are conveyed by a rubber tube to another tambour fixed on a stand and this in turn actuates an optical lever on which a beam of light is projected. The magnified excursions of the optical lever are recorded photographically. Fig. 1, A, is a record of the movements of the cartilage in singing up and down an octave. Now, if instead of singing audibly I think of the notes of the octave, and at the same time record the laryngeal movements, I shall obtain a similar picture (Fig. 1, B). The movements are generally smaller than in actual singing, and for purposes of comparison they have been roughly magnified three times in this figure by moving the recording cylinder further away from the optical lever.

FIG. 1.



THOUGHT A MODE OF MOVEMENT, WHETHER VOCALISED OR SILENT.

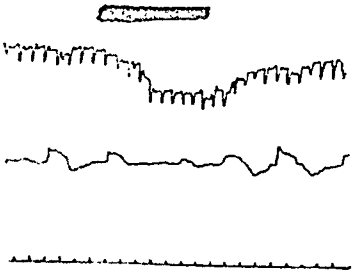
Thought is expressed either by external or internal speech, and whether the speech be externalised or internal it is a mode of movement. If I recite to myself a speech or a poem I can demonstrate the occurrence of similar laryngeal movements, though in this case their relation to the corresponding speech movements cannot be demonstrated with the same ease. Now to think of the notes of an octave or to recite a poem silently is not quite the same thing as to sit quietly and think over any problem or make arrangements for the future. In the first case we are trying to represent to ourselves every tonal step of the octave and every word of the poem, whereas in the latter we are not so concerned with the verbal niceties of our problem as with the conclusions to which it leads. Our motor manifestations in the second case will be more sketchy, the hint of the beginning of a word movement will be sufficient to convey to us the sensory impression of the word just as in reading psychological experiments have shown that the eye does not move along the line of print from letter to letter; but that in a series of jerky movements it seizes sufficient letters to allow of the recognition of any one word and then darts on to the next. The

less prone to take umbrage at a harsh expression than is the auditive.

CONNEXION OF MUSCULAR TENSION WITH INTELLECTUAL OR PHYSICAL EFFORT.

I next propose to deal with those movements that connote a generalised reaction of the organism, from the study of which I think we can gain much information as to the fundamental disturbances of mechanism in the neuroses. In the first place I will invite you to study those organic reactions by which the body responds as a whole to stimuli occasioned by the vigorous activity of some specific mechanism. To denote this form of response I prefer to avoid any terms that have subjective implications, such as attention and conation. I shall therefore speak of this type of reaction as effort, and distinguish for purely methodological reasons intellectual and physical effort.

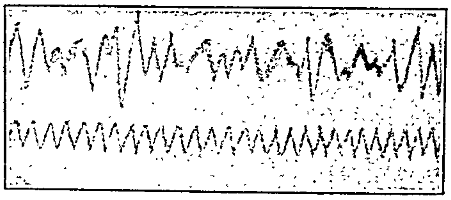
FIG. 5.



The upper tracing is that of the movements of the foot. A downward movement of the lever indicates an upward movement of the foot. The lower tracing is that of the respiration. Time in seconds. Thick black line indicates approximate duration of stimulus—a multiplication.

That effort is accompanied by some general alteration of muscular tension has been generally appreciated in a vague fashion, but I have found no record of any attempt to measure and determine the nature of these alterations. Now, there is a very simple and homely method by which the alterations of tension in the quadriceps muscle can be verified. Everyone has at some time or other noticed that when the legs are crossed in such fashion as to allow the crossing leg to hang almost freely downwards the foot can be observed to pulsate up and down with every beat of the pulse; the lower leg, in fact, constitutes the lever of a sphygmograph. If when the legs are so adjusted as to show the pulsation and we are reclining comfortably in an armchair in front of a tiled fireplace we carefully observe the height of the pulsating toecap against the line of intersection of the tiles, we can readily verify any change in the level of the foot. Now, still keeping the eye on the alignment between the toecap and the crevice in the tiles, make some voluntary effort—either attempt to perform some difficult piece of mental arithmetic or grip some object with all your force. It will be seen that coincidently with the effort there has been an appreciable upward movement of the foot—that is, a shortening of the extensor muscles of the thigh has occurred. It is quite easy to measure this shortening and to determine its nature. To do so, it is above all necessary to ensure that the crossing leg is completely relaxed and that the lower extremity is hanging sufficiently freely to exert a constant pull on the quadriceps tendon. This state is present when the foot can be observed to be pulsating vigorously with each heart beat, and is brought about by taking care that the free suspension is in no wise interfered with by the underlying knee supporting the calf muscles. The knee of the crossed leg should lie in the upper part of the popliteal space of the crossing leg. The toecap of the shoe is then attached by a thread to a suitably placed lever whose excursions are reco[illegible] the kymograph. A shortening of the quad[illegible] ward movement of the foot will be re[illegible] downward movement of the lever. [illegible] d of the quadriceps shortening mani[illegible] pe of effort, the solving of a problem [illegible] metic. It is now necessary to inquire [illegible] of this contraction of the quadriceps; is it of the nature of a so-called voluntary contraction—that is to say, produced by direct cortical innervation, or is it due to an increase of postural tonus? The work of Wertheim Salomonson has shown that it is possible to differentiate between these two types of muscular contraction. It was shown by Piper that the electromyogram of a voluntary contraction as recorded by the string galvanometer is manifested by an irregular oscillation having the frequency of roughly 50 vibrations per second. These vibrations were considered by Piper to indicate the number of motor nerve impulses reaching the muscle in a second. It is for many reasons certain that they really indicate nothing of the sort, but they served Salomonson to differentiate a voluntary muscular contraction from a tonic contraction which he proved to be entirely innocent of these vibrations. Fig. 6 represents a record taken by the Bock Thoma oscillograph of the vibrations occurring during a voluntary contraction of the quadriceps. In order to investigate the nature of the quadriceps contraction in effort, I recorded simultaneously the movements of a lever connected with the toecap and the electromyogram obtained by a string galvanometer connected with needle electrodes plunged into the substance of the quadriceps muscle. During the effort contraction produced by a dynamometer squeeze it will be seen that there is no trace of the Piper vibration, and we are entitled to speak of the effort phenomenon as a tonic contraction (Fig. 7). The electromyogram is, moreover, of some considerable interest, as it shows a phenomenon that I have verified in all my records of tonic contractions—at the commencement of the tonic contraction, as evidenced by the movement of the lever, there is a current of action of the order of about 0·1 millivolt. The current of action is of much longer duration than the diphasic variation of a single muscle twitch. Its duration is about 0·4 sec. It will be noted that after it has subsided the galvanometer registers a perfectly straight line in the position of rest, although the lever registers a continuance of the tonic contraction. It is of some importance to know the nature of the nervous mechanism responsible for this

FIG. 6.



Electromyogram of a voluntary contraction. Below time in 0·01 secs.

Upper line is that of movements of foot. Downward movement of lever indicates an upward movement of foot. Lower line is the shadow of galvanometer string. Time in ½ seconds.

LIB

Croonian Lectures

ON

THE OBJECTIVE STUDY OF NEUROSIS.

Delivered before the Royal College of Physicians of London on June 9th.

BY F. L. GOLLA, M.B. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE I.[1]

IN this series of lectures I propose to deal with certain types of movement that are the manifestations of those phases of cerebral activity which have been generally considered to be confined to molecular changes in the cerebral cortex and its great ganglia. I refer to processes of thought and feeling. The modern knowledge of the functions of the brain has led us to look to this organ almost exclusively for the manifestations of mental activity; we are apt to forget that to such a great psychologist as Aristotle the brain was nothing but a mass of cold matter whose function was to cool the blood coming from the heart and lungs, serving only as an intermediary link between the organs of sight, smell, and hearing, and the heart where their sensations were perceived. It is through our concentration on the cerebral aspect of mental activity that we have been so slow to realise that the body partakes in the movements that express this activity and, by ignoring these bodily signs, the possibility of establishing an objective standard in our interpretation of neurotic disturbance is, to a great extent, lost. What, then, are data furnished by objective observation of the activity of the nervous system? I cannot do better than quote the views of Bergson as summarised by Hoffding: "All that takes place in the surrounding world and in my own body, including my brain and nervous system, consists only of movements of different kinds and degrees. From the external world movement is spread abroad through our body. It reaches the spinal column and the brain by way of the sense organs and the nerves, and proceeds into peripheral movements. Our body is an instrument which receives movement from the outside, and restores it to the external world. There is not from this point of view any difference between the brain and other parts of the body. The brain is merely stronger than the other organs in preserving the action that it has thus received, and does not always reproduce them in movement immediately but often makes them coöperate in ulterior movements. The body, including the brain, is an instrument of movement and nothing else. To no degree, in no sense, from no point of view, does it serve to prepare and still less to explain a representation. That which, in our perceptions, can be explained by the action of the brain, includes the actions which are commenced or prepared or occasioned, but not our perceptions themselves. Still less does the activity of the brain comprise any explanation of memory and of higher mental activity. If everything in the brain and outside is movement we must not look for anything else than what is observable. The nervous system has only physical properties, and has no other power than that of receiving, preserving, and continuing movement. Movement alone is sensible to us and movement can produce nothing but movement. The whole effect of physical processes is exhausted by the effort of motive adaptation (le travail d'adaptation motrice). If the brain is ill, it is only movements and nothing else that are arrested." No scientific worker is likely to quarrel with this view, but it is important to realise that its adoption leaves us untrammelled by any metaphysical implications; it is as consistent with materialism as with idealism, with monism as with dualism.

RELATION OF PSYCHOLOGY TO PHYSIOLOGY.

It will be plain that a psychology founded on this objective basis leaves untouched all that constitutes for us the chief interest in life. In terms of objective psychology such expressions as meaning and purpose can find no place; by severing it from teleology, history, from the point of view of the psychologist, will become unintelligible. This was, indeed, the view of psychology held by Münsterberg, who argued that the sole function of psychology is to provide us with mechanical uniformities of sequence by the aid whereof to calculate the future behaviour of our fellows in so far as it is not modified by fresh purposive initiative, and that the whole of psychology is a temporary stop-gap, by which we eke out our defective physiology, but which must sooner or later cease to be of use, and therefore cease to exist, as physiology advances. Indeed, to such a pitch must psychology necessarily be brought, if we listen to the warnings of Avernarius on the besetting sin of "introjection."

Now this may or may not be a desirable state of affairs for the psychologist, but I maintain that for us as physicians it is the only possible. The late Dr. Mercier entitled his text-book of insanity "Disorders of Conduct," for of mind he said he knew nothing. It may, indeed, be held with some plausibility that there are no such things as disorders of mind. As physicians we are confronted with cases exhibiting disorders of conduct that is of the mechanism of expression, and our psychology must stand in exactly the same relation to mechanism as does our physical science. It is necessary to insist on these methodological points because we find both neurology and, to a lesser degree, physiology in a state of great confusion owing to their non-observance. Consider the mess that neurology has made of the subject of aphasia, by a careless use of physiological and metaphysical concepts. It arose merely because neurologists talked of memory—a non-physical entity—being stored up in nerve cells without realising that they were talking nonsense. All that they were really entitled to say is that the mechanism of representation is preserved in certain neurones.

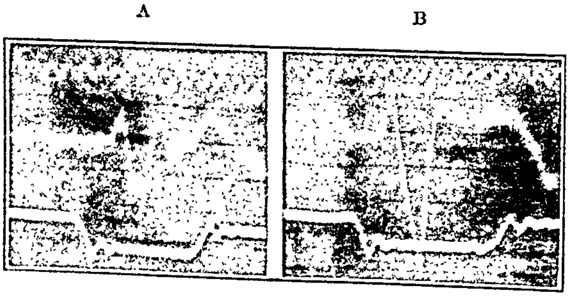
PHYSICAL DISTURBANCES THE PRIMARY FACTOR IN THE NEUROSES.

Thanks to the labours of Pierre Marie, and in more recent times to those of Head, we are slowly reconstituting our knowledge of aphasia as being in all its forms a disorder of the mechanisms of expression. It is interesting to note that we have only now arrived at the same conclusion on the subject of aphasia as that advanced by a philosopher, M. Bergson, nearly 30 years ago, as soon as he detected the confusion of thought that lay at the root of our difficulties. It is from much the same causes that so much confusion arises in physiological literature on the subject of sensation—that is, from the incautious use of non-physical terms in the description of physical states. The point of view that I am about to deal with in these lectures has for its object an attempt to define in objective terms the chief data that may lead us ultimately to formulate the nature of the physical disturbance of mechanism that constitutes the primary factor in the neuroses. That such a physical disturbance is the cause of the neuropathic condition and precedes its manifestation I hold very strongly. One fact emerges from all the investigations that have been conducted in recent years by the methods of analytical psychology, and that is that in the vast majority of cases the experiences of the neurotic differ in no way from those that fall to the lot of ordinary healthy men. The data furnished by the war are often cited as an argument to the contrary, but I think that they really furnish irrefutable evidence that an organic disturbance or failure of organic equilibrium preceded the manifestation of the neurotic symptoms and could not have the tendon reflex response is universally admitted, though the current explanation that finds acceptance among neurologists is very unsatisfactory. We are always told that in consequence of the voluntary effort the inhibitory power exercised over the tendon reflex are by the cortex is relaxed, and hence the response is increased. We know, however, from clinical evidence that the magnitude of the tendon reflex varies directly with the degree of tonus, and I have shown that one sign of effort is an increase of muscular tonus. In order to obtain an exact comparison of any two reflexes it is necessary that the stimuli should be of equal magnitude. I constructed a pendulum hammer which when released at the same angle could be trusted to hit the patellar tendon with uniform force. The moment of occurrence of the stimulus was indicated by the hammer closing an electrical circuit which actuated a Deprez signal when it struck a piece of metal foil that was pasted on to the patella. Fig. 12 shows the tendon reflex at rest and during effort. It will be noted that in addition to an increased response during effort there is a shortening of the latent period from 20σ to 15σ. This shortening of the latent period presents some difficulty as to its interpretation. If we assume with Piper that the velocity of a nerve impulse is 120 metres per second, and with Jolly and Hoffman that the latent period of the receptor organs and that of the muscle is about 11σ, we obtain values for the synaptic time lost in the cord of about 4σ. Now, the shortening of the latent period in the second of these two reflexes is of such a magnitude that it is very difficult to ascribe it to a diminution of the lost time in the central nervous system, and the same remark applies to the effector muscle and the receptor nerve-endings. Even if we consider that the diminution is spread over all three, its magnitude is very great in comparison to the total time involved. There is no reason to suspect the measurement of the velocity of the nerve impulse of any marked degree of inaccuracy, because it is confirmed by the comparison of the latent periods of the achilles tendon reflex and the knee-jerk in the same individual when the increased length of the latent period in the first reflex corresponds to the additional nerve tract traversed. I have found similar concordant differences in measuring the latent period of the triceps-jerk and the knee-jerk in the baby. Whatever be the explanation, the effort tonus reflex appears to be associated with an increased velocity of response as well as an increase of magnitude, in as far as these simpler reflex mechanisms are concerned. While the diffuse tonic reflex that we have been discussing tends to cause extension of the limbs, the position of the head in effort is differently affected.

---

[1] The succeeding lectures will appear in THE LANCET.

FIG. 12.

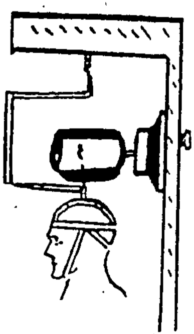


Upper record is the electro-myogram of the knee-jerk, elicited A, when resting; B, when engaged in muscular effort. Lower record is the signal. Time in 1/100th of a second.

EFFORT AND HEAD MOVEMENTS.

To study the head movements the subject was seated in a high-backed chair and to the vertex of a wire skeleton skull cap the free end of a piece of wire was connected by allowing it to lie loosely in a small brass tube soldered on to the vertex. The other end of the wire was fixed in a freely moving ball-and-socket joint on a wooden support fixed directly over the head. The wire was so curved as to allow a small recording drum to be at right angles to its axis, so that a writing point fixed to the wire immediately above its joint with the skull cap wrote directly on the smoked surface of the drum (Fig. 13). With this arrangement the only head movements that can be recorded are those which take place at right angles to the direction in which the drum is revolving. With this rather primitive instrument I had to obtain two successive records of the response to the same type of stimulus in order to obtain the resultant head movements. I soon found, however, that the lateral movements of the head are of irregular nature and bear no relation to effort. When, however, an effort, whether muscular or intellectual, is made there is a slight but definite forward movement of the head which lasts for the duration of the effort. The absence of the vibratory action currents characteristic of voluntary contraction in the sterno-mastoids has led me to consider this movement to be tonic in nature, but the difficulty of exploring the small flexor muscles of the head will not allow of dogmatic statement. The bowed head observable in certain people when thinking deeply is obviously an exaggeration of this reflex.

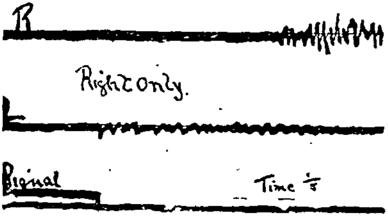
FIG. 13.



EFFORT AND RESPIRATORY MOVEMENTS.

The relation of the respiratory movements to effort has long been known, and a series of observers have studied the alterations of the respiratory curve in the hope of finding distinctions typical of different mental states. Time does not allow me to criticise these records in detail; I can only subscribe to the generally expressed want of faith in the existence of special types of respiratory curve associated with specific mental states. There is, however, one factor on which everybody is agreed, and that is the reduction of the amplitude of the respiratory movements associated with effort. The usual method of observing respiratory changes by recording the movements of the thorax and abdomen is, however, inconvenient. The apparatus concentrates the attention of the patient on his respiration, and the net effect of the respiratory movements on intrathoracic pressure can only be estimated by the correlation of thoracic and abdominal tracings. In fact, one observer, Rehwoldt, uses no less than five tambours placed on different portions of the thorax and abdomen. The method I have adopted allows the total respiratory variation to be estimated with a minimal amount of disturbance to the subject. A soft rubber No. 1 catheter tube is fixed to the upper lip by a piece of plaster so that its free end is on the same plane as the aperture of the nostril. The tube is connected with a Marey tambour and the pressure alterations in its air column caused by inspiration and expiration are recorded. After the first few minutes the subject is almost unaware of the presence of the apparatus, whereas the knowledge that the chest wall is influencing a tambour applied to it produces a curious concentration on the respiratory movements that as a matter of personal experience I have never been able quite to eliminate. The net results of the effect of effort on the respiratory movement are shown in Fig. 5 with a simultaneous record of the quadriceps tonus. The tidal air is reduced to a minimum and the respiration is slowed. We are all aware that when we attempt to perform any very delicate manipulation or some particularly exacting calculation we have a sensation of holding the breath and that the termination of a short effort of this description is followed by a prolonged expiration—a sigh of relief. Some years motor manifestations constitute what Ribot has happily termed the skeleton of our presentations. What, then, fills in the skeleton outlines? The answer varies for each individual. Ask a number of men to think of a given multiplication sum—some of them will see the figures, others will hear them, others will combine a feeble visualisation with a certain sense of movement, feeling as if the eye were travelling down a row of figures and each were visualised in turn in its place. Those who manifest most markedly laryngeal movement probably fill in the gaps of the skeleton with kinæsthetic representations of the vocal movements that do not actualise. The rôle of actual speech movements in representation is probably under-estimated. Had I been asked some years ago before I had considered the question in what way I represented to myself the octave I should have answered unhesitatingly that I heard it, I have now little doubt but that my laryngeal movements are the first link in evoking the ultimate auditory representation, because though I am told that I have a fairly good ear, my musical memory is to a great extent limited to the representation of those notes that lie in the compass of my voice. Similarly, in visual representation our visual images appear to be to a great extent stimulated by kinæsthetic images arising from the centres for movements of the eye muscles and in extreme cases the stimulation of the motor cell may translate itself into actual movement. I have often performed the experiment of asking an unsophisticated subject to describe to me Trafalgar Square as he would see it if he stood at the base of the Charles I.'s monument. If one is careful to avoid standing exactly face to face, and thus allowing him to fix his eyes on the observer's, in nine cases out of ten I find that as he reels off the series of objects to be seen his eyes move from the right when he mentions Morley's Hotel, to the left when he comes to the Union Club, and upwards as he describes the Nelson monument. It is not only in the mechanism of internal speech that we find these movements, but in the preparation for action. Figs. 3 and 4 represent the results I obtained in some experiments in which the subject was asked to dorsiflex both hands the moment he heard a sound signal. Both forearms were lying with the palms downwards on the table and the extensor group of each forearm was connected to two galvanometers which were constituted by two of the loops in an oscillograph. In the case illustrated the patient was a left-handed man, and in the experiment recorded in Fig. 2 he was asked to raise the right hand only when the signal sounded. It will be observed that from the time that the signal sounded till the actual moment that the right hand was raised there was a well-marked electrical vibration observable in the extensor group of the left arm. The idea of movement in this subject was represented by an actual activation of the muscles, and as he thought of all his movements primarily in terms of the left hand, it was the left extensors that responded. When he was asked to dorsiflex both hands simultaneously, we again see the representation of movement in the left hand (Fig. 3). On asking him to move the left hand alone, the same left-sided representation occurred (Fig. 4). It appears that this connoted the idea of movement on which he was concentrating, and was not in any way a preparatory performance, since the latent times of moving the left hand alone and the right hand alone were identical. In a right-handed subject the phenomenon was reversed. It is of interest to note that for reasons that I shall deal with when we come to talk of tonus one can be sure that this motor representation was of the nature of a voluntary muscular contraction, not an increase of muscle tonus. This motor representation has its influence on all our forms of thought. A very cursory survey of the expressions that we use, whether in the language of description or of abstract reasoning, is enough to show that a dynamic symbolism is universal.

FIG. 2.



Some time ago Binet made some observations on chess players who were able to play several games blindfold and simultaneously. We should anticipate that such men had an abnormally acute power of visual representation; but though they all stated that they could without much difficulty visualise the chessboard, they agreed that in actual play they never did so, and that visualisation would, if anything, rather impede than help them. The chessboard to them was represented in dynamic terms as a congeries of contending forces. A knight was a force acting diagonally and a rook vertically. I do not intend to pursue the subject of these specific forms of motor reactions further, because, as I said before, their disturbances belong more appropriately to the study of gross organic lesions; but it must not be assumed that the specific mechanism by which representations normally occur is without influence on the symptomatology of the organic disturbance which, I hope to show, underlies the neuroses. As to the nature of this influence on conduct I will confine myself to one hint. A surgeon with world-wide experience of the congenitally blind once told me that when a blind man was vicious his abnormality often assumed forms more gross and detestable than occur among the sane with normal eyesight. I have the impression that men with a predominantly auditory type of representation are less nice about physical matters than those with a predominantly visual type, and that the visualist is less nice about the choice of words and

FIG. 3.

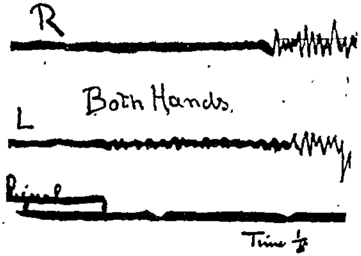


FIG. 4.

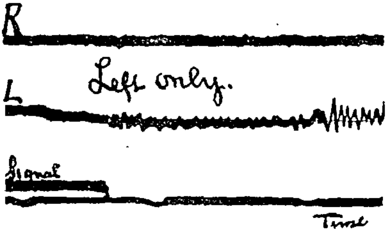


response to cerebral activity have been much studied, and the observations of Lehman and Weber—to mention only two of the writers who have most concerned themselves with plethysmographic studies—agree in recording a fall in the volume of the limb as a sign of effort. The vaso-constriction continues throughout the period of effort, and should the effort have been sufficiently intense to cause discomfort its cessation is followed by an increase in the limb volume to a greater size than before the beginning of the effort. We shall consider this after-effect when we study the objective signs of affective states. Weber has recorded alterations in the intra-abdominal pressure accompanying cerebral activity which he ascribes to a variation in the blood-supply to the intra-abdominal viscera.

EFFORT AND VISCERAL REACTION.

What we have seen of the increased muscular tonus during effort and the respiratory variations makes any interpretation of results obtained by introducing balloons into the hollow viscera exceedingly difficult. That many important visceral changes accompany cerebral activity is, of course, certain, in fact, they constitute the most important part of the bodily accompaniments of such activity, but so far their investigation has to be conducted by methods adapted to show chemical rather than gross motor variations. Lange has described fluctuations of the "active sense attention"—sinnliche aufmerksamkeit—the existence of which is shown by the fluctuating appearance and non-appearance in consciousness of a minimal sense impression. I have objectively demonstrated fluctuations of effort; for this purpose the subject was instructed to hold a wand in his hand and to keep the point of it in the middle of a small ring, suspended from a stand. The ring was lined on the inside with a hollow thin-walled rubber bag, which was blown up to a low degree of tension and connected at its orifice with a recording tambour. The quadriceps tonus and the respirations of the subject were recorded on a drum together with the pressure in the bag. A slight movement on the part of the subject would lead to the wand touching the bag and the increment of pressure was recorded by a movement of the tambour lever. When the touches on the ring bag were most frequent there was a diminution of the quadriceps tonus and an increase in the depth of the respirations. The back of the subject was turned to the drum so that he could not observe what was taking place. In this fashion it was possible to demonstrate fluctuations of the effort coinciding with periods of inaccuracy in the handling of the wand. Such periods became more frequent as the subject became fatigued, and in certain cases of neurosis complaining of nervous asthenia they were particularly frequent.

I have so far endeavoured to give some brief account of the movements that are the objective expression of effort. The first portion of my next lecture will be devoted to the consideration of the relationship of such movements to the sensory phenomena that are the concomitants of mental and physical effort.

DUBLIN UNIVERSITY WAR MEMORIAL.—The manner in which the 450 members of the College who fell in the war are to be commemorated has now been decided. The memorial is to take the form of a Hall of Honour in connexion with a reading-room, to be built when funds permit. The hall, placed between the library and the theatre, will extend some paces into the Provost's garden. A design by Sir Thomas Deane has been adopted, which, while not impairing the architectural dignity of the library, will provide a beautiful as well as a useful building. Between £5000 and £6000 have been subscribed, but a much larger sum will be needed. A large number of additional subscribers are hoped for now that the precise form which the memorial is to take has been announced.

The Gold Medallists' War Fund, which has no connexion with the official College memorial, amounts to over £1400, and will be used to help in educating the sons and daughters of the Trinity men who died in the war. A list of all those who served has been prepared, and will be published at the end of the long vacation. Prof. M.W. G. Fry will be glad to receive any additions to it that are sent to him at Trinity College, Dublin.

Lumleian Lectures

ON

SOME POINTS IN THE ÆTIOLOGY OF SKIN DISEASES.

Delivered before the Royal College of Physicians of London on March 10th, 15th, and 17th, 1921,

BY ARTHUR WHITFIELD, M.D., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE, SKIN DEPARTMENT, KING'S COLLEGE HOSPITAL.

LECTURE II.*

I MAY now turn to some of the internal factors in the production of skin diseases. There is, I think, little doubt that until recently the internal factor has been to some degree slighted by the specialist in diseases of the skin, a fact easily explicable for three reasons. In the first place there is the great difficulty of tracing any constitutional change in most cases. In many skin diseases there are no very obvious accompanying signs or symptoms of defective health to guide even the most patient and thorough investigator. Secondly, I think I may say that in most of the simply inflammatory skin diseases the success of local treatment compared with that of internal is very striking, and this will naturally attract attention more to the local lesion than to the constitutional state. Thirdly, the expert in skin diseases is so frequently seeing diseases of purely local origin, such as scabies, ringworm, &c., treated as due to some obscure constitutional condition that he is apt to become prejudiced against internal factors as a potent cause.

In attempting to deal with the internal factors in the ætiology of diseases of the skin one becomes immediately conscious of the fact that any kind of attempt to form an orderly arrangement is a matter of extreme difficulty. It would seem natural to suppose that a certain definite defect of health would call forth the same cutaneous symptoms as a constant result.

This is, however, by no means the case, and we constantly see different cutaneous disorders associated with the same defect in the health of other organs, and also the same cutaneous diseases associated with one of several internal lesions. Thus diabetes may undoubtedly call forth diseases so different as furunculosis and xanthoma, whereas scarlatiniform erythema associated with fever may be caused by streptococcic tonsillitis or the ingestion of quinine.

After some consideration I have come to the conclusion that perhaps the least confusion will arise if I deal with the ætiological factors more or less consecutively, and indicate those dermatoses which are frequently associated with, and, in my opinion, are partly due to each.

SENSITISATION.

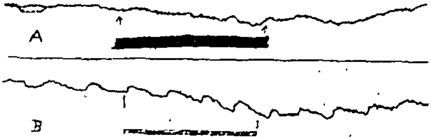
1. *Auto-sensitisation.*—I begin, therefore, with the question of eruptions due to sensitisation, and before dealing with sensitisation to bodies introduced from without I should like to draw attention to a short series of cases illustrating what I believe to be a form of auto-intoxication derived from changes in the patient's own tissues. As far as I know this type of poisoning has not previously received any attention.

The first case that I encountered was that of a young lady who received a severe blow with a cricket ball on the shin. The result of the blow was to produce a hæmatoma which was not accompanied by any breach of surface. Nothing further occurred for ten days, when there suddenly appeared a generalised, morbilliform, erythemato-urticarial eruption, strongly resembling that resulting from the injection of diphtheria antitoxin. On being consulted with regard to her skin trouble I made every investigation that I could think of into her diet, general health, and history, reflex, and this, unfortunately, must at present remain a matter of great uncertainty. Boeke has found in voluntary muscles nerve endings which appear to be of sympathetic origin, and there is some reason to believe that the centrifugal path of the tonic reflexes is guided by sympathetic fibres; but in spite of the suggestive work of De Boer the question must be regarded as still open. I have found this tonic effort reflex much increased in cases of unilateral pyramidal lesions on the affected side and very much diminished, but still quite definite in cases of tabes. In a case of cerebellar tumour with very marked unilateral hypotonus placed at my disposal by my colleague, Dr. J. S. Collier, the effort reflex was absent on the hypotonic side and normal on the sound side. In the case of the flexed knee, it appears that the tonus of the extensor group is alone increased, while that of the flexor muscles, which by virtue of the position of the leg are already in a state of greater tonus than the extensors, is unaffected or diminished. It is of some interest to determine whether this distribution of tonic innervation occurs elsewhere. If the forearm be flexed at the elbow and supported on a block, and the completely relaxed hand be allowed to hang over the end of the block in a position of supination, it is easy to obtain a record of the hand movements by attaching the lever thread to the head of the middle metacarpal by a pellet of wax. In such a case it will be found that dorsiflexion of the hand occurs in response to effort, whilst when the hand is supinated and allowed to fall backwards over the edge of the block a flexion of the hand at the wrist results (Fig. 8, A and B).

---

* Lecture I. appeared in THE LANCET of July 9th, p. 61. Lecture III. will appear in a subsequent issue.

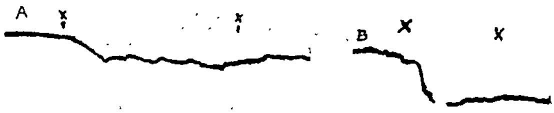
FIG. 8.



Tracings of A, tonus reflex of flexor; B, of extensor muscles of wrist during mental effort. A downward movement of the lever indicates an upward movement of the hand.

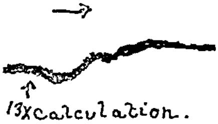
In the case of the elbow-joint, which like the knee-joint only permits movement through one half of a circle, the tonic effort reflex may be demonstrated in the triceps when the upper arm is supported at right angles to the body and the lower arm is allowed to hang downwards. The tonic effort reflex, as shown by the wrist-joint experiments, only affects those muscles which are in a stretched condition. I will next consider what happens when the limb is in a position in which the tonus of the antagonistic groups of muscles is presumably equal. To investigate this point it was obvious that movements of the extremities could no longer serve as indicators; it was therefore necessary to devise some method for the direct measurement of alterations of muscle tonus.

FIG. 10.



A, increase of tonus in flexors of wrist. B, increase of tonus in extensors. Stimulus between × — × — calculation.

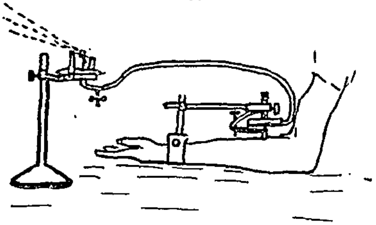
FIG. 11.



MEASUREMENTS OF ALTERATIONS OF MUSCLE TONUS.

It is obvious that for this purpose the registering apparatus must not vary its position in relation to the muscles of the limb, as otherwise a slight involuntary shifting of the limb would be interpreted as an alteration of muscle tonus. To secure this end, in the case of the forearm a suitably devised clamp was fastened firmly to the bony prominences formed by the heads of the radius and ulna. From the clamp a light rod projected backwards to hold a tambour, with a spring attachment that controlled the pressure, with which a short rod was pressed into the flesh over the belly of the muscle to be investigated. The free end of the rod was in contact with the centre of the tambour membrane. Any increase of the tonus of the muscle would press up the rod, and the resultant air displacement in the tambour was conducted by a tube to a delicate Marey tambour fixed on a stand. In place of the ordinary writing lever over this capsule an optical lever was substituted, consisting of a light mirror fastened to the middle of a piece of silk stretched immediately above the tambour. From the back of the mirror projected a short lever 2 mm. in length, actuated by a short reed projecting from the middle of the tambour membrane. By such an arrangement the air displacement, due to movements of the rod resting on the muscle, could be magnified to any desired extent, and a similar apparatus attached to the antagonist muscles allowed simultaneous records of the alterations of tonus to be taken (Fig. 9). The photographic records (Fig. 10) show that with the wrist-joint in the neutral position there is a simultaneous increase of tonus in both antagonistic groups of muscles of the forearm. Similar records have been obtained from the majority of the more accessible skeletal muscles. The effort reflex appears to increase the tonus of all those muscles that are in a stretched or a neutral state. Fig. 11 is a photographic record of the increase of tonus during an attempt to say the "thirteen times" multiplication table. The subject was a very poor arithmetician; the first three or four stages were rattled off with ease and no increase of tonus appeared, but as the difficulty of the multiplication increased the effort showed itself in a gradual increase of the muscle tonus. I have many records that show a similar correspondence between the degree of tonus and the intensity of the effort put forth, and we shall see later that in certain neurotics who are incapable of prolonged or intense effort the tonus reflex is correspondingly affected. Now as to the significance of the reflex—I have a very strong aversion to all forms of teleological explanations not confirmed by direct observation. One result of the increase of tonus is, however, fairly obvious. The influence of muscular and mental effort in increasing

FIG. 9.



other substances that they had never ingested. In such cases the eczema clearly was not due to the substance producing the reaction. Therefore, unless we can reproduce the second half of the experiment and cause the disappearance and reappearance by the withholding and administering respectively of the specific protein, as was done in the case of the cabbage-eating patient, we are not justified in assuming that the eczema is due to the ingestion of this protein.

I have in this relationship an interesting case of what I call a natural experiment.

A baby aged three months was brought to me for acute eczema of the face and head and a little on the body. The history showed that the eruption began about one week after the acme of development of his vaccination vesicles at the age of four weeks. He had been nursed for five weeks, i.e., one week after the outbreak of the rash, and after that was fed on raw cow's milk and water, cream, limewater, and sugar of milk. It is important to observe the fact that this baby's rash appeared before he drank any cow's milk. It has been suggested, and the suggestion appears to be not without probability, that the use of calf lymph as a vaccine may cause some sensitisation to protein from the cow, either in the milk or in the flesh of the animal. In this case there were no symptoms of indigestion and no constipation. The eczema proved very resistant and the child was brought to me seven times in eight months. Recently the interesting discovery has been made that the child is sensitive to egg. As he was doing well and was getting to a more advanced stage of feeding he was on one occasion given a small quantity of yolk of egg. This was followed immediately by intense vomiting and after a short interval by diarrhœa, and the child was ill for two days, but no exacerbation of his eczema followed. On a subsequent occasion he was given a small amount of custard, and this was followed by a similar train of symptoms, but again no apparent immediate or remote effect on his eczema.

Now here, therefore, we have a child who is suffering from eczema and who is "egg sensitive." Yet not only is his eczema not due to egg as it preceded its ingestion, but the ingestion of the offending protein makes him ill without affecting his skin.

Quite recently I have come across a second case of "egg sensitiveness" in a baby 14 months old, suffering from eczema. In this case the egg also makes him ill and gives him urticaria, but does not aggravate the eczema.

Secondly, there is a difficulty somewhat the converse of this. If we take the case of a patient who is sensitive to substance x, and in whom substance x causes a skin eruption on ingestion, we find that this was not always the case. The sensitiveness is not congenital, nor is it the consequence of any acute attack of poisoning from eating x in a state of decomposition. I suggest that in this type of case there is present either a gastro-intestinal error, so that x is broken up into noxious cleavage products, or that there is some inefficiency in the detoxicating function of the liver.

I have a curious example of this type of case in a middle-aged lady.

Some years ago this patient began to develop attacks of urticaria, usually of short duration. There was no history of acute poisoning or apparent gastro-intestinal error. After a considerable time the patient discovered the cause herself, and found that it lay in the ingestion of any kind of tinned meat or soup. Tinned fruit such as peaches or pineapple are without evil effect, as are also tinned sardines, but the ingestion of tinned beef or soups is followed in about three hours by an outbreak of urticaria, which dies away next day if no further tinned meat products be taken.

There is no question in this case of suggestion, as I have known her state (always correctly) that there has been tinned soup at dinner by the fact of her suffering from urticaria a few hours later, and she has been unaware that there has been anything tinned in the dinner until the rash has come out. Others partaking of the same food have in no instance been affected.

GASTRO-INTESTINAL ERRORS.

In relation to derangement of the alimentary canal there appear to me to be two types of case, namely, the irritative and the toxic, though these occasionally overlap. Some of the examples in the [illegible] group are fairly clear in their causation. Such are the cases of rosacea of the strongly angio-neurotic type. The patients are usually, but by no means always, of the female sex. The ingestion of a hot drink, especially tea, or of a highly condimented dish such as curry, or of an acid white wine, is followed in a few moments by an intense flushing of the face, usually affecting especially a triangular area in the middle of the forehead, the nose, the cheeks contiguous to the nose, and the middle of the chin.

The type of dermatosis which develops on this flush area has seemed to me to be dependent on the previous condition of the skin. Those with a naturally thin, dry, and fresh-coloured skin develop a papulo-squamous eruption associated with soreness, itching, and burning, whereas those whose skin is naturally thick, greasy, and pale tend more to the development of severe seborrhœa and pustulation. There is, however, a point here worthy of attention, namely, that this second class of case may be easily confused with a true acne of middle life which is not accompanied by flushing, and belongs, in my opinion, to the second or toxic class of eruptions due to derangement of the gastro-intestinal function.

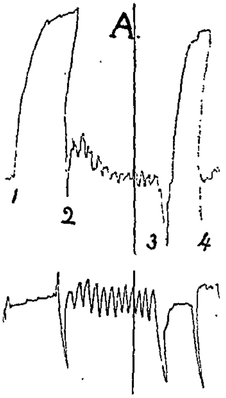
Ryle and Barber[10] have published a paper on rosacea, giving the results of gastric analysis in 12 cases. In 10 of these abnormal curves of hydrochloric acid production were found, and of these 7 showed extreme hypochlorhydria. Grouping achlorhydria and hypochlorhydria together, they found them present in 58 per cent. of the cases of rosacea.

I cannot agree with Barber's clinical description. He states that the patients have broad, flabby, pale tongues, marked by the teeth at the edges. Now I have paid great attention to this point, both before and since the publication of his paper, and I find it to be quite exceptional in what I consider the markedly angio-neurotic cases. It is, on the other hand, very commonly present in the cases which I regard as toxic acne, with a pale, lemon-tinted complexion and little or no flushing, and it is present in some of those border-line cases which show slight flushing and marked toxic symptoms. Barber admits that the fact that the flushing often occurs almost immediately after the ingestion of food is in favour of a reflex mechanism, but he suggests that it is possible that it is partly or wholly due to the absorption of vaso-dilator substances, such as alcohols formed by the fermentation of carbohydrates by yeasts, sarcinæ, or bacteria in the stomach or small intestine. He also thinks that the effects of oral sepsis and tonsillitis should be remembered in connexion with rosacea, thereby, in my opinion, revealing a confusion between the angio-neurotic and toxic types of eruption. The toxic type is much more variable as regards the cutaneous symptoms. It is also much more difficult to be precise as to the presence and variety of the toxæmia.

The methods that I have chiefly used are the testing of the urine for indican, urobilin, and bile salts, and its examination for bacterial infection, and also, in a certain number of cases, examination of the fæcal flora. I have found indican absent in every case in which there was no apparent reason in either the general or cutaneous condition of the patient to suggest a toxæmia. On the other hand, I have found it present in low or high degree in the most diverse cases of cutaneous eruption, so that one must be careful in attributing the eruption to the toxæmia. Also I have very frequently failed to find it present in cases where one might have suspected its presence a priori.

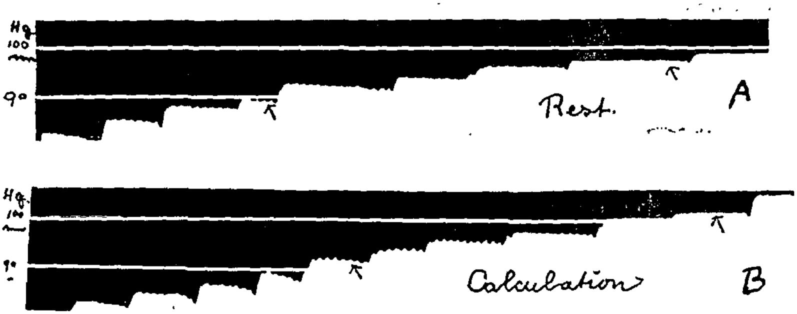
The chief cutaneous diseases in which I have frequently found it have been cases of irregular erythema, lupus erythematosus, pruritus without objective signs, widespread and obstinate acne, and very occasionally in psoriasis. In none of these diseases is the ætiology precisely known as yet, and there is a strong suspicion that all may be due to toxic absorption from some source. I should state at once that I am not for one moment suggesting ago, when I conducted some researches on the phagocytosis of carborundum particles under different conditions, I found that the respiratory reaction during the performance of counting the particles ingested in a number of leucocytes was the most irksome part of the proceedings. This flattening of the respiratory curve is not to be attributed to a simple diminution of the respiratory movements; it is conditioned by the general increase of muscular tonus, affecting primarily the expiratory muscles, whilst expiration is obstructed by closure of the glottis. The result is an increase in the intrathoracic pressure. On two occasions I have connected a manometer with the needle in cases in which paracentesis of the thorax was being performed for pleural effusion. In each case any voluntary effort on the part of the patient was accompanied by a well-marked rise of the intrathoracic pressure. The expiratory and inspiratory oscillations were markedly decreased. Turning to the effect of effort on the intracranial pressure we see what are the results of these respiratory changes. In the spring of 1914, together with W. L. Symes, I made some observations on the alterations of pressure of the cerebro-spinal fluid on a number of cases of cerebral syphilis who were being treated by the then fashionable remedy of injection of salvarsanised serum. Hitherto all observations of the intracranial pressure have been made with patients who have been trephined, and the pulsating skin and membranes over the trephined area have had their excursions directly recorded by a tambour. The advantages of the estimation of the pressure of the cerebro-spinal fluid by lumbar puncture in the intact organism over this method are sufficiently obvious, and its delicacy is very much greater. We examined in all six cases and found that the cerebro-spinal pressure responds to the slightest physical or intellectual effort by a marked rise. Our observations showed moreover the great influence of respiration on the cerebro-spinal pressure. Fig. 14 shows well the enormous fluctuations that occur with deep inspirations and expirations and the huge rise when the breath is held. The increase of the intrathoracic pressure during effort is the chief if not the only cause of the concomitant rise of intracranial pressure.

FIG. 14.



Simultaneous records of the cerebro-spinal pressure (upper line) and the respiration (lower line). Between 1 and 2 breath was held, 3 and 4 are deep inspirations.

FIG. 15.



Photograph of pulse oscillations of mercury column at different pressures of Riva-Rocci bag A when subject is at rest. B during calculation. The arrows point to beginning of pulsation and to the maximum oscillation.

EFFORT AND CIRCULATORY REACTION.

Since the fundamental work of Mosso the response of the circulatory system to cerebral activity has been the subject of a great deal of investigation. The increased frequency of the heart to intellectual effort is well shown in the slide. It is of some interest to discover whether this increased frequency is determined by accelerator stimulation or by removal of the vagal control. For this purpose I took some records with a much faster rate of movement of the photographic paper than in the record shown, and measured the time relations of the systole and diastole. Reid Hunt found that by stimulating the accelerator nerve the times of systole and diastole are decreased together, while with a loss of vagal control the loss of time is confined to the systole. My records all show that the systolic time is unaffected, whereas the diastolic time is diminished; thus the effort is responded to by a diminution of vagal tonus. The blood pressure is again very generally known to be increased in effort, and we shall see that in certain types of neurasthenia this increase is either very small or absent. The criticisms of Pachon have shown that the method commonly practised in this country of taking the records of the pulse at the wrist while the artery is compressed higher up is unsound; this is particularly true when investigating the changes accompanying effort and affective states in which there is reason to believe that vasomotor changes at the extremity of the limb are most marked. On the other hand, to record the pulse at the site of the application of pressure, that is, from the pulsations communicated to the Riva Rocci bag, precludes the use of tambours whose sensitiveness is affected by variations in internal pressure. For this reason I have connected the bag with a mercury manometer and photographed the pulsations (Fig. 15). It will be noted that contrary to the observations of Schrumpf and Zabel the systolic and diastolic pressures are both increased. It does not appear to me to be possible to apportion the relative degrees of influence exerted by the heart and the vasomotor system in this reaction. The vasomotor changes in the peripheral circulation in the ordinary intermittent pressure on the finger tips causes it to bend up at the tip and sides so that it becomes curved in a direction opposite to the normal. As a rule the nail-bed appears unaltered, but in some cases there is a varying degree of hyperkeratosis with separation of the plate from the bed.

The first case of this peculiarity appeared in my clinic at the Great Northern Central Hospital many years ago, and in searching for an explanation, I was struck by the fact that the patient, a middle-aged woman, had been many times in hospital for gastric ulcer and severe hæmatemesis. Since then I have seen a sufficient number of patients with this trouble to convince me that it is not a mere coincidence. In fact, in the last two cases I have been able to prophesy from looking at the nails that we should get a history of severe hæmatemesis. It is, I admit, difficult to understand the relationship of the two symptoms.

INTESTINAL ANAPHYLAXIS.

Before leaving the gastro-intestinal canal I may refer to the brochure recently published by Dr. DANYSZ[12] on the origin, nature, evolution, and treatment of chronic non-parasitic diseases. In this small work Dr. Danysz brings forward the view that many diseases of chronic nature in which a parasitic cause has not been found are due to the production of a state of anaphylactic immunity, and that they owe their origin to excess of immune substance in the blood. He considers that the main source of this is the alimentary canal, and that owing to congestion and functional disturbance proteid bodies are absorbed without being broken down sufficiently far into their component amino-acids, a view that I had already written in an earlier part of these lectures before seeing his book. Instead, however, of regarding the eruptions as due to the direct poisonous action of these bodies, he considers their action as antigens and invokes the production of excess of immune substance in the blood and a state of anaphylaxis to account for the skin lesion.

His method of treatment is to cultivate the easily grown fæcal organisms in such cases, to mix them in roughly the same proportion' as that in which they are found in the fæces, to kill them by heating to 70°C., and to use the resulting mixture as a vaccine. He describes a long list of cases treated by this method and gives a great number of successes.

Having read an earlier paper by Dr. Danysz on the same method, claiming the successful treatment of pemphigus and dermatitis herpetiformis, I tried it some years ago on a very typical and resistant case of the latter disease, and failed to find any effect whatsoever as a result.

At the present time I have a male patient under my care in hospital with a somewhat suppurative, symmetrical dermatitis and marked arthritis. This case resembles in type some of those in which Dr. Danysz claims his cures. Accordingly, after the patient had been under observation in bed for some time so that we could form an idea as to the course of his disease, we made a vaccine, following out Dr. Danysz's directions very carefully. This was administered hypodermically in the way and at the intervals recommended. The course is now finished, and the patient thinks it has done him good, but I confess I see no marked improvement as the result. At all events the eruption and the arthritis are still very obviously present and the suppuration has not stopped. Any alteration for the better is certainly in the subjective condition of the patient, and not in the objective signs.

On the other hand, in favour of Dr. Danysz's views, I feel that it is but just to refer to the fact that Dr. Barber showed at the Dermatological Section not long ago, some cases of psoriasis in which the treatment by this method had been followed by an improvement not obtained by any of the ordinary measures. It is, for me, difficult to follow the reasoning. If the sensitisation and consequent dermatosis are caused by the accumulation of excess of immune body or amboceptor, and the anaphylactic shock in severe cases caused by the sudden meeting of this excess with antigen, it is difficult to understand how the preliminary injection of a very small fraction of the usual dose of antigen acts. One would imagine a priori that this minute dose of antigen would only fix a correspondingly minute proportion of the excessive amboceptor, leaving a great mass to combine with the large subsequent dose, and produce the anaphylactic shock in only slightly less intensity.

Another difficulty also offers itself to my mind. Dr. Danysz reports improvement after ingestion of the vaccine by the mouth, though he considers subcutaneous injection the more potent method. If the administration of the dead bodies of those micro-organisms is therapeutically effective when administered by the physician, why is it not so when they are absorbed in the ordinary course of events from the patient's own intestinal canal?

I do not offer these objections to the theory as reasons against the practical use of the method if it be found to be beneficial after more extensive experience, but I protest against his off-hand assumption that the vaccine treatment of Wright depends on no kind of specific immunity reaction and only on this desensitisation.

XANTHOMA AND CHOLESTEROLÆMIA.

I may conclude this lecture with a reference to the work which has been done in elucidating the ætiology of a disease presumably connected with the alimentary canal—namely, xanthoma.

For many years this curious change in the skin has attracted the attention of the specialist. As far as I can ascertain Pinkus and Pick[13] in 1908 were the first to suggest that the body giving some of the staining reactions of fat was not an ordinary fat but a cholesterol ester. Pringsheim,[14] also in 1908, stated that this cholesterol ester was deposited in the tissues from the blood. In 1910 Cranston Low[15] of Edinburgh wrote an excellent article on the subject and corroborated the statement that the fat-like body was a cholesterol ester of a fatty acid. He pointed out that more apparent fat was found by means of staining with Sudan III than with osmic acid. He also referred to the nodules found in the heart, and suggested that a cardiac murmur heard in his case was due to this cause. In 1912 Chauffard and Roche[16] claimed that the disease was probably caused by an excess of cholesterol in the blood, though this was not apparently proved. They also assumed that it was due to a lypolytic insufficiency of the pancreas.

Rosenbloom in 1913[17] appears to have been the first to publish an estimation of the cholesterol in the blood in xanthoma multiplex. Curiously enough, he found in a case of G. H. Fox's that there was "no increase of cholesterol in the corpuscles and plasma compared with the normal control." His figures were as follows:—

	Cholesterol.	Cholesterol ester.
Xanthoma corpuscles ..	.. 65	Trace
Normal control ..	.. 68	"
Xanthoma plasma	.. 48	22
Normal control ..	.. 46	28

giving in the total blood:—

Xanthoma .. .. 135 | Normal control .. 112

In 1920 Dr. Burns[18] published a further report of a very severe case of xanthoma tuberosum in which estimations were made of the cholesterol in the blood. The patient's blood was estimated after 14 hours' fasting at the end of a week on three different diets. The blood uric acid was high, 4·3 mg. per 100 c.cm.; the blood sugar was 0·091 per cent.; cholesterol was found in the nodules in large quantities. Two estimations of the cholesterol in the blood after a week on the ordinary mixed diet gave:—

Cholesterol.	Fat.
(1) 660 mg. per 100 c.cm. = 0·66 %	2000 mg. = 0·2 %
(2) 650 mg. per 100 c.cm. = 0·65 %	1700 mg. = 1·7 %

The normal controls showed:—

Cholesterol.	Fat.
210–240 mg. per 100 c.cm. = 0·2 %	300–400 mg. = 3·4 %

The xanthoma patient showed on the low fat diet:—

Cholesterol.	Fat.
660 mg. per 100 c.cm. = 0·66 %	1400 mg. = 1·4 %

On the high fat diet:—

Cholesterol.	Fat.
999 mg. per 100 c.cm. = 0·99 %	1000 mg. = 1·0 %

Since this paper of Dr. Burns's, the high blood content of cholesterol has been confirmed by other and was finally reduced to the possibility that it might be connected with the absorption of broken-down tissue at the site of the bruise. The matter had to be left there for the moment as no further evidence was forthcoming.

Some time later I saw another lady who had fallen down stairs and damaged her left wrist, producing severe ecchymosis without breach of surface. Again on the tenth day the general erythema appeared, precisely as in the former case.

These two cases put me on to the track of this curious association, and since then I have seen three other cases due to aseptic trauma, and I believe, though of course it is much more difficult to prove, many due to trauma where the surface had been broken, and microbic infection might also perhaps be invoked. One of this latter class of case, seen with Dr. C. R. Verling-Brown, of Sutton, may be quoted as an illustration.

An elderly gentleman suffered from an irritable, but not purulent, eczematous dermatitis of the leg. Under suitable treatment this had been brought nearly to the point of cure. Then one day after his bath he thought that a brisk rubbing of the part with a rough towel would stimulate the circulation and hasten the complete recovery. The result of this injudicious treatment was a certain amount of swelling of the part accompanied by a little hæmorrhage and serous exudation. In eleven days' time a generalised eruption appeared, the individual lesions consisting of millet-seed-sized hæmorrhagic papules, associated with urticarial erection of the follicles, and intense itching. When I saw the patient the site where he had injured the original patch had settled down again, and it showed no sign of active sepsis. The skin of the body and limbs generally was covered with small petechial scratched papules which might have been diagnosed as eczema after an insufficient examination. Factitious urticaria was present to a slight degree and irritation was intense.

Such a case as this might well be ascribed to septic absorption, and had I not seen the aseptic cases, two of which I have quoted, I might have put it down to this cause, but as the matter stands I am confident that the physical damage to the tissues was the prime cause. I may add that this case, as well as all my others, except the first in which it was not tried, yielded rapidly to the internal administration of turpentine, a drug which in my experience is the only one with anything approaching a specific value in toxic purpura.

The question which I am entirely unable to answer is why this sensitiveness to the products of one's own bruised tissues should develop. It was not a congenital peculiarity in any of my cases, for I inquired carefully into this, and in every case there was of course a history of many bruises that had not been followed by a general cutaneous disturbance. At the same time I would submit that this is not a valid objection to the correctness of my view, since there are cases in some of which the poison is accurately known where the sensitiveness has developed for some reason entirely unknown.

Lest it should be thought that these cases are in reality merely coincidences to which I am attributing an erroneous explanation, I venture to mention another, but I think allied, phenomenon as to which I have direct experimental evidence. It is of course well-known that in vesicular eczematous dermatitis without marked pyogenic infection the rash spreads from one part to another in an apparently capricious manner. There are also, I may add, instances brought to one's notice from time to time in which there has been some degree of apparent contagiousness in the eruption. Those persons dressing cases of weeping eczema occasionally develop a similar eruption, usually of only a fleeting nature, on the hands. This spread is due, in my opinion, to the locally irritant nature of the eczematous discharge, which is generally toxic for the patient, rarely so for other people, and only for those who are probably of a peculiarly susceptible type. The most convincing case that has come into my experience was one of true gouty eczema, that is, in an elderly gentleman who suffered at the same time from classical acute gout in the toe and vesico-bullous eczema of the legs.

It was noticed that when his bullæ burst and the serum drained down across the legs there appeared in a few minutes a red streak which was followed in about ten minutes by the development of an urticarial wheal, and this in turn was succeeded first by a line of vesicles and then by a long narrow bulla. In order to put a stop to this process I drew off the serum from his bullæ with a sterile hypodermic syringe, and I wondered one day whether this fluid was irritating only to his skin or also to that of the normal individual. Having obtained a syringe full of this clear serum I therefore allowed this to trickle down my own forearm and dry on, and was interested to observe that this procedure was followed by no subjective symptoms or objective signs. This patient was then, I think, undoubtedly sensitive to his own tissue products, whereas I was not.

In this connexion I may draw attention to the fact that quite recently Dr. W. J. O'Donovan showed at the Dermatological Section a case of dermatitis herpetiformis, the diagnosis of which was generally accepted. Dr. O'Donovan himself remarked, however, that he hesitated a little about it as the disease was auto-inoculable, and that if he inserted fluid from a vesicle into another part of the skin it produced an outbreak locally. Dr. J. M. H. MacLeod suggested that this was not due to inoculation, but merely to the slight trauma inflicted. My explanation of this experimental production of the lesion is that it depends upon the patient's sensitiveness to his own morbid serum.

I attribute considerable importance to this series of cases, because I believe that some of the cutaneous rashes ascribed to the absorption of bacterial toxins from septic foci are in reality due to absorption of damaged tissue, though in the present state of our knowledge the disentanglement of the two agencies is impossible.

FOREIGN PROTEIN SENSITISATION.

I may now pass on to the effects of what has been termed protein sensitisation in the sense of a susceptibility to certain forms of protein introduced from without. I have myself carried out no experimental work on this subject, and as far as I am aware most attention has been devoted to it in the United States, where a large amount of painstaking work has been done. The method employed has been to take a large number of proteins derived from different articles of food and to inoculate them separately into the superficial part of the skin.

Fox and Fisher[9] used commercial proteins from various animal and vegetable sources. They scarified the epidermis, not deeply enough to draw blood, in lines one-eighth of an inch in length. On these they placed small quantities of the respective proteins and moistened them with a drop of N/10 caustic soda to facilitate absorption. At the end of half an hour the mixture was washed off and the results watched, control scarifications of course having been made. The smallest reaction admitted as positive was a wheal 0·5 cm. in diameter, and this appeared after a variable number of hours. They tested in this way to some 25 varieties of food protein 60 patients, of whom 41 gave entirely negative results, and 19 reacted positively to one or more proteins.

The most satisfacory result was in the case of a man who suffered from eczema and gave a strongly positive reaction to the protein of cabbage. This patient was in the habit of eating large quantities of both ordinary cooked cabbage and sauerkraut. They found that by alternately withholding and administering cabbage they could cause the disappearance and reappearance of his eczema at will. Fox and Fisher finally concluded that "It would appear to us that they (the tests) will ultimately prove to be of therapeutic assistance in a small proportion of eczema of adults." They also suggest that it may be of more general significance in the eczema of infants.

For all this careful and exacting work I have the highest respect, but there are a few words of warning which I think it fair to offer. The authors themselves draw attention to the fact that in some cases infants with eczema reacted to carrot and of the blood cells from the thirtieth week onwards might show the change from fœtal to infantile conditions to be sufficiently regular to form a basis for computing the period of development reached at birth. This inquiry could readily be carried out at a lying-in hospital, and might very well yield results of great practical value both to the obstetrician and the medical jurist.

Lying-in hospitals give a glimpse of the premature infant only from birth to the end of the second, or perhaps the end of the third week. Figures of gross mortality are of little practical value until they have been split up into the two groups, indicating (1) *mortality at birth*, including macerated fœtuses, non-viable fœtuses, and those which, though born alive, did not survive their birth (stillborn); and (2) *mortality in infancy*. The former is very largely uncontrollable; improvements in obstetric management might possibly enable a certain number to be saved, as in cases of toxæmia, ante-partum hæmorrhage, and syphilis. A very large number of premature infants are, however, non-viable when born. Group II. is the one with which we are chiefly concerned, and the gross mortality in this group, estimated in the reports of six hospitals, stands at the appalling figure of 40 per cent. In other words, nearly half the premature babies born alive in lying-in hospitals die before the end of the third week of life. Examination of the reports, however, shows that in this gross mortality are included a large number of infants so handicapped at birth as to have but a slender chance of survival. Thus, premature babies born in maternal toxæmia, or in labour with ante-partum hæmorrhage, cannot be said to start life with a fair chance of survival; in addition, there is a small number of infants born with serious developmental defects, or with a congenital syphilitic taint, and these are also severely handicapped from the start. We shall come nearest to an estimate of what are the chances of survival for a baby whose only drawback is prematurity, if we exclude these conditions, and correct the gross mortality figures accordingly.

Table II. shows (1) the gross infantile mortality, (2) the "corrected" infantile mortality for premature babies, and (3) the gross infantile mortality for babies born at term, "correction" of the figures being unnecessary in this latter case, as the maternal complications mentioned above are relatively very uncommon in labour at term.

TABLE II.

	Premature Babies.		Mature babies (per cent.).
	Gross mortality (per cent.).	Corrected mortality (per cent.).	
Hospital A (London)	41	34·0	1·8
Hospital B (Provinces)	41	—*	3·6†
Hospital C ″	46	38·0	0·7
Hospital D ″	30	—*	0·8‡

* No data for correction.
† This figure is quite abnormally high.
‡ O.P. Department (Extern maternity).

These figures show that from 30 to 45 per cent. of premature babies die in the lying-in hospitals; and if a selection is made of those premature babies which have no obvious disability in addition to their prematurity, on an average of two hospitals, less than two-thirds survive their third week. The percentage mortality of these selected premature babies during this period may be anything from 35 to 50 times as great as that of mature babies born under the same or similar conditions.

Induction of Premature Labour.

A certain number of premature births are the result of induction of premature labour for slight degrees of pelvic contraction. These are carefully selected cases, the gestation period being, in all but a very few, 36 to 38 weeks, the condition of the mother being good, with no complication apart from the pelvic contraction. These cases would, therefore, be expected to yield better infantile results than those just set forth. They come out as follows, and it is clear that these particular figures need no "correction": Hospital A (London), 14 per cent.; hospital B (Provinces), 36 per cent.; hospital C (Provinces), 20 per cent. The average of the three hospitals is about 23·3 per cent.

A certain small number of deaths are included in these cases, which occur during labour as the result of the birth process, or of obstetric interference, but they are too few to affect the percentage appreciably.

While these results are on the whole better than the "corrected" figures of premature infantile mortality it cannot be contended that they are satisfactory. The object of inducing premature labour in pelvic contraction is to obtain, with the minimum of risk to the mother, an infant that will survive. If the infant does not survive, the principal object of the operation has not been obtained. A percentage mortality of 14 is low enough to justify the procedure, but a percentage mortality of 36 condemns it. Perusal of the reports shows that at hospital A, with the lowest mortality-rate, a large number of inductions are done as late as the thirty-ninth and fortieth weeks. In the other two hospitals all but a very few inductions were done at the thirty-fifth and thirty-sixth weeks. This difference goes far to explain the more favourable results obtained at hospital A.

It would be of great interest to determine the relation between the mortality and the degree of prematurity, if the data could be obtained. In only one of the hospital reports are the returns presented in a form which enables this point to be investigated, and the numbers are, of course, very small. The following result was obtained:—

Week.	Percentage mortality.	Week.	Percentage mortality.
35th	33·3	38th	7·0
36th	18·1	39tb	10·8
37th	12·5		

These are all cases of induction for pelvic contraction, and the figures indicate that before the thirty-sixth week the infantile risk is much too heavy to be faced, and therefore one of the other available obstetric operations should be preferred in degrees of contraction which call for induction at such an early period. The figures show how rapidly the mortality-rate falls from the thirty-fifth to the thirty-eighth weeks, and this is, of course, to be expected in the nature of things. The rise in mortality-rate from the thirty-eighth to the thirty-ninth week is also not without significance to obstetricians.

Confirmatory evidence of this result may be found along parallel though not identical lines. One of the hospital reports furnishes a record of the progress of all *undersized* infants arranged in groups according to their weight at birth (Table III.).

TABLE III.

Class.	—	Total.	Dead.	Percentage mortality.
I.	5½ to 5¾ lb. (36 to 38 weeks).*	149	12	8·0
II.	4¾ to 5½ lb. (34 to 36 weeks).*	89	11	12·3
III.	4 to 4¾ lb. (32 to 34 weeks).*	77	26	33·7
IV.	3½ to 4 lb. (30 to 32 weeks).*	51	27	51·0
V.	2¾ to 3½ lb. (28 to 30 weeks).*	35	33	94·2

* Represents the approximate period of gestation at which this weight is usually reached.

Of course, it will be understood from what has been said in an earlier part of the note that babies may be born at term which are under the normal weight, and therefore the above figures are not that abnormal intestinal decomposition is the invariable cause of any of these conditions. I am quite clear from a long series of urinary examinations that indicanuria is not invariably associated with any one of them, and, as I shall mention later on, in some of these conditions I have met with other defects of health which I believe to have been quite definitely the cause.

INDICANURIA IN SKIN DISEASES.

It may be of use to give some illustrative cases of various diseases associated with indicanuria. I will deal first with psoriasis, and here I may mention that some 15 years ago I found that there was a small proportion of cases of psoriasis in which the eruption disappeared after the ingestion of creosote. In one case patches on the knees of nine years' duration, which had resisted internal treatment with arsenic and many forms of external treatment, disappeared in a few weeks while the patient was taking creosote. A long series of cases showed me, however, so few in which favourable results could thus be obtained, that the use of creosote for this disease almost ceased to be one of my methods, more especially as I was quite unable to distinguish any particular type in which it would be probably of some use. Since using the indican test with regularity, I find that it is only very rarely that indicanuria is associated with psoriasis, but it appears to be precisely in these exceptional cases that creosote is of value.

A male patient, aged 43, came to me suffering from psoriasis which had been slight for many years and severe for two. On the first occasion I treated him very successfully with arsenic internally, although he had a severe attack of herpes zoster while taking his highest doses. He did not remain quite clear, but kept his slight relapses under control with local treatment only. Seven years later he had another severe attack, and returned to the arsenical treatment and again cleared up almost entirely in two months. Nine months after this attack he developed another severe attack which did not yield at all to arsenic, even in very high doses. I tested his urine, and to my surprise found it went almost black with indican. I therefore put him on creosote, and in a fortnight his rash was somewhat improved though the indican was still present. Three weeks later the rash was gone and the indican had also disappeared. I have not seen him since to ascertain whether in this case the indican and the psoriasis accompany one another as a rule.

A second case occurred only very recently in my practice. The patient was a female, aged 27, who had suffered from psoriasis since she was 14 years old, and had therefore had a great deal of treatment of various kinds. The eruption was severe, and had been so for two months. The urine, somewhat to my surprise, turned almost black when tested for indican, and I therefore tried her with creosote. In five weeks' time she wrote to tell me that she was practically clear.

Now I have already said that it is only quite exceptional for me to find indican in the urine of psoriasis patients, and it is also only rarely that creosote is of value in psoriasis. I therefore think that there is more than coincidence in these cases, and that, although not the prime cause of psoriasis, the intestinal decomposition was the final determining cause of the particular outbreak.

With regard to lupus erythematosus, this is also a disease in which I have not very commonly found indicanuria present, but in those cases in which it has been present it seems to have been a valuable indication. The following appears to me to be an instructive case.

A lady who had been subject to great nervous strain developed a rather diffuse attack of lupus erythematosus on the nose and cheeks. She had lost a great deal of weight, but had no special symptoms beyond obstinate constipation. Fearing the tuberculosis which is so often associated with this disease, I had her thoroughly examined by an extremely expert physician, who found no evidence of tuberculosis. I then had her nose, throat, and teeth examined. The former showed nothing beyond some deviation of the septum, while the dental surgeon found some chronic periodontitis in one or two teeth. These were put right without any benefit accruing as regards the skin lesions. The bacteriological examination of the fæces showed a normal flora, but the urine gave a strong indican test. Treatment was then started, first by freezing with CO_2 snow and then by one or two other local methods, but none of these proved very efficacious. She was then put to bed for a month, carefully shielded from sunlight and cold winds, and this for the first time produced slight but definite improvement, with a small gain of weight. The improvement was, however, neither great nor well sustained, and soon after she got up she developed a fresh patch on the palpebral conjunctiva—not, in my experience, a very common situation for lupus erythematosus. Then, for the first time, she was put on creosote, which she took without trouble. In a short time the disease was completely arrested and the patch on the conjunctiva and several of the smaller patches on the cheeks disappeared. The weight rose steadily, and when for a short time salol was substituted for the creosote the gain in weight ceased, but returned when the creosote was resumed. This patient has not made a complete recovery as yet, but she has improved so much that she is no longer noticeably disfigured. Repeated examination of the urine has shown that indicanuria is no longer present. The nerve strain is, however, unfortunately continuing to a certain degree, and this I think militates against the cure.

I have given this case in some detail because Dr. Barber[11] believes that lupus erythematosus is a disease associated with the presence of *Streptococcus longus*, and in certain cases I believe this to be correct. This patient has had the examinations in each speciality carried out by one of the leading men, and in each case an ardent believer in the doctrine of focal infection, but we have none of us been able to find the *Streptococcus longus.*

Indicanuria is also not uncommon, in my experience, in urticaria and in pruritus without external evidence, and in connexion with the latter I have had one very interesting case.

This was in a young lady who suffered tortures from pruritus but showed no eruption at all. Finding very marked indicanuria I put her on to creosote with the, to me, astonishing result that the pruritus was very much worse, and she developed an urticarial eruption. The creosote was dropped and resumed, and the urticaria disappeared and reappeared concomitantly. Remembering that creosote is excreted mostly as sulphate, I conceived it possible that the drug took up some of her sulphuric acid and thus aggravated her trouble. I accordingly stopped it and put her on largish doses of sulphuric acid, and, post hoc or propter hoc, she was greatly improved.

PRURITUS ASSOCIATED WITH THE PRESENCE OF BILE SALTS IN THE URINE.

One other case of pruritus may be mentioned in connexion with urinary abnormality. In this instance I found in a case of obstinate pruritus that bile salts were present in the urine. Having read that the administration of thyroid gland was beneficial in this condition I ordered it and was gratified to observe the disappearance of both the bile salts and the pruritus. The case occurred many years ago, and of course the work bringing the matter to my notice is still older, but since then I have added the simple sulphur test to my routine examination of the urine, and I have never come across another case, so I think it must be a very rare condition.

BACILLURIA.

Before leaving the urine I may mention the frequent association, especially in women, of chronic urticaria with *Bacillus coli* infection of the urinary tract. This is so common that I think it should be carefully sought after in every chronic case. Some of the patients do very well for a time with inoculation, but it is difficult to discover how much of the good result is due to specific immunisation and how much to "proteid shock." At any rate I have found that a second course of inoculation, undertaken for a relapse of the disease after apparent cure, has been in my hands useless.

THINNING OF THE NAILS ASSOCIATED WITH GASTRIC ULCER.

I should like here to call attention to one other abnormality connected with the gastro-intestinal canal, more especially as I have not seen it recorded anywhere. This is a peculiar thinning and delicacy of the finger-nails. The nail-plate, without developing any ribbing or roughness, becomes so excessively thin that raspatory, and the sternal end of the clavicle disarticulated. Care must be taken not to injure the large vessels lying behind these structures. Thus loosened, the sternal end of the collar-bone, together with the skin flap still attached to it, is retracted upwards by means of a strong hook or a strip of gauze. The whole region of the subclavian vessels, anonyma included, and the brachial plexus becomes easily accessible. The details will be indicated in the following account of a case.

An officer, aged 26, suffered a gunshot wound on Nov. 11th, 1919. The bullet entered from the back, near the fourth dorsal vertebra, and came out one inch above the sternal third of the right clavicle, after which he spat blood, and his right arm became paralysed. There were no signs of aneurysm. On May 2nd, 1920, closer investigation of the nerve condition resulted as follows: Complete anæsthesia of the hand, except in the median area, where slight sensibility remained. Anæsthesia of the external half of the forearm (cutaneous branch of the radial nerve) and of the lower and external part of the deltoid region (axillary nerve). In the other parts of the arm normal or nearly normal perception was maintained. Very well-marked atrophy of all the muscles of the hand and the forearm—except of flexor digitorum communis profundus, which was less affected and probably made possible the very slight movements in the fingers. The deltoid muscle and the flexors of the humerus were also markedly atrophied, and also, in less degree, the triceps, which gave a very slight extension of the arm, after the forearm had been flexed passively. No other movement was possible in the arm. On the basis of this examination I inferred that all the nerves of the brachial plexus had been injured in greater or less degree.

Operation (6/5/20), under chloroform anæsthesia. The incision was made and the sternal end of the collar-bone disarticulated, as just described. Having retracted the skin and muscle flap upwards, together with the mobilised sternal end of the clavicle, we cut the fascia and the clavicular muscle on a director, tied and divided between two ligatures the external posterior jugular vein, and then the omo-hyoid muscle at the level of its tendon. After the two branches of arteria transverse colli and several small veins had been cut between two ligatures, the brachial plexus appeared at the bottom of the wound. It was found to be injured in its external part and compressed all round by cicatrices. The plexus was cleared from scar tissue, the injured part reconstructed by means of several stitches, and all this portion of the plexus protected from new adhesions by a flap of adipose tissue, taken in the neighbourhood. Having replaced the collar-bone and fixed the sterno-clavicular joint by two stitches, we closed the wound, with a drain left in its outer part for 48 hours. The arm was fixed to the trunk for two weeks. Healing took place by first intention. As the collar-bone seemed to protrude a little forward, a sandbag was applied to the sterno-clavicular joint with a satisfactory result. About three weeks after the operation the first definite movements appeared in the hand and fingers, which have since continued to progress.

This case shows that the method (to which I first drew attention in 1916) for operating on the subclavian vessels is also available for reaching the brachial plexus.

This observation illustrates the advantages afforded by temporary disarticulation of the inner end of the collar-bone, over the method of section of the bone usually practised; while affording freer access to the whole supra- and infra-clavicular regions, it disturbs their anatomical relations very little and, for an experienced surgeon, is very easy of performance. It is advisable, in order to protect the clavicle from subsequent dislocation, to stitch it firmly in place and to immobilise the arm for at least two weeks.

DONATIONS AND BEQUESTS.—The late Dr. Henry Barnes of Carlisle, vice-president and formerly president of the British Medical Association, and president of the Cumberland Infirmary, left his medical books to the Royal Society of Medicine; £50 each to the British Medical Benevolent Fund, the Medical Auxiliary of the C.M.S., Epsom College, and the Border Counties Home for Incurables, Carlisle. In the event of the failure of trusts for his wife and children, he left, among other bequests, £1000 to Cumberland Infirmary, £2500 to Edinburgh University for a Scholarship for Clinical Medicine, and £1500 [illegible] College for a similar scholarship.

TWO CASES OF ACUTE HÆMORRHAGIC PANCREATITIS

AND ONE CASE OF PANCREATIC ABSCESS.

By ALWYNE T. COMPTON, F.R.C.S. ENG.,
SURGEON, GERMAN HOSPITAL, LONDON;
AND
FRANK HEBER, M.R.C.S., L.R.C.P. LOND.,
HOUSE SURGEON TO THE SAME HOSPITAL.

THE prognosis of acute pancreatitis in its various forms is grave and always uncertain. Of cases which appear to be clinically and pathologically identical probably the greater number die even after early operation. Others, although they finally recover, give rise to the gravest anxiety during the first few hours or days. Others again, a small minority, make a speedy and uninterrupted recovery. In a disease with such clearly defined and striking symptoms and signs it seems strange—as has often been remarked—that the diagnosis should be so seldom made before operation. It is therefore fortunate that the true nature of the case can practically always be recognised as soon as the abdomen is opened.

One of us (A. T. C.) has recently analysed 50 cases of acute pancreatitis recorded between 1910 and 1920 in eight of the most accessible British journals. At the operation fat-necrosis and ascitic fluid (usually blood-stained) are the two findings which attract immediate attention.

Fat-necrosis, either in the omentum, mesentery, or retro-peritoneal tissue, was found in 33 out of 35 cases subjected to operation. Blood-stained fluid, either in the lesser sac, the greater sac, or both, was found in 17 cases; "turbid" fluid in one, and "bile-stained" fluid in one. The condition of the pancreas itself is variously described as simple swelling, acute inflammation with or without cyst-formation, hæmorrhagic pancreatitis, abscess, or more or less extensive sloughing of the gland. Of six, definitely mentioned as cases of acute hæmorrhagic pancreatitis, three died and three recovered. In this series of 35 cases treated by operation, pancreatic fistulæ are stated to have developed only in two. One, a man of 51, in whom a cyst containing trypsin was found, had a fistula for four months, the amount of discharge of pancreatic fluid varying from 2 to 17 oz. daily. The other case, a male of 40, had a fistula for six weeks. Both fistulæ appear to have closed spontaneously.

In the case about to be described a fistula persisted for nearly six weeks and gave us the opportunity of verifying one or two facts relating to the physiology of the pancreas. For the first three weeks or more the pancreatic juice was mixed with pus and other discharge. Therefore the time available for our observations was limited to a few days only.

CASE 1.—Mrs. G. M., a Polish Jewess, aged 37 years, was admitted to the German Hospital on May 11th, 1920, suffering from intense epigastric pain with vomiting. There was nothing important in the family history. She had never been ill before. There were five children, the youngest being 5 years old.

History of present illness.—About the middle of April, 1920, the patient had an attack of pain in the epigastrium lasting for several hours and accompanied by vomiting of greenish fluid. As the bowels were not open she took magnesium sulphate. The pain and vomiting ceased entirely, and nothing unusual was noticed till the evening of May 10th, when she was again seized with the same violent pain. The onset was sudden, the pain described as an "intense cramp," accompanied but not relieved by vomiting of the same kind of greenish fluid. This condition persisted all through the night and the following day.

Condition on admission.—At 9 P.M. on the 11th the patient was much exhausted by incessant pain and repeated vomiting. The face was pale but not anxious. The tongue was dry, the pulse rather small and rising in frequency from 130 to 110 during the first hour after her arrival. By artificial light the colour of the skin and conjunctivæ could not be accurately made out, but on the following morning a very faint yellow tinge was visible. Examination of the observers, and it is now generally believed that the tumour-like growths are due to the irritation of the tissues by the deposit of cholesterol in them. At the discussion on Dr. Burns's paper it was pointed out that xanthoma-like masses had been produced by feeding rabbits with cholesterol and then inflicting local injury to determine the site of the deposit. I do not think that the pancreatic lesion has as yet been studied, but all the evidence points to its presence. It has also been suggested that xanthoma diabeticorum is not caused by the sugar disturbance but by the cholesterolæmia which accompanies it.

We seem therefore to be on the high road to elucidating the ætiology of one more of the puzzling skin lesions.

A NOTE ON THE MORTALITY OF PREMATURE INFANTS.

BY THOMAS WATTS EDEN, M.D., F.R.C.P. LOND., F.R.C.S. EDIN.,
OBSTETRIC PHYSICIAN, CHARING CROSS HOSPITAL.

THE only source from which detailed information on this subject can be gathered is the medical reports of the lying-in hospitals. The greater number of such hospitals in the United Kingdom issued reports before the Great War broke out, and I have been able to examine figures from six different institutions. The statistics cannot be brought up to date, because in most cases publication of the reports has not yet been resumed. In some of the reports the figures are presented in a form which makes it very difficult to gather from them any detailed information. The total number upon which the figures given below are based is accordingly small—too small indeed to permit me to claim that they are anything more than an approximation. They will, however, serve at least to show how heavy is the mortality of premature babies born in the lying-in hospitals, in comparison with that of the mature babies.

Difficulties of Accurate Obstetric Calculation.

A serious inital obstacle has to be encountered in the difficulty of deciding, in many cases, whether a baby is premature or not, and in the affirmative case, what is its degree of prematurity. The ordinary obstetric calculation from the last menstrual date has a possible margin of error of roughly three weeks—corresponding to the length of the menstrual interval. Calculation from the last coitus is also open to error, for spermatozoa can remain alive in the fallopian tubes for a considerable period. Dührssen found active spermatozoa in the tubes of a woman operated upon three and a half weeks after the last coitus. It is known that in rabbits spermatozoa can survive in the uterus for from 8 to 10 days, and Dührssen's observation is not therefore inherently improbable. Both these errors tend to over-estimation of the duration of gestation—that is, they make the number of premature babies born appear to be lower than it really is; e.g., it would appear that the fortieth week has been reached when it is really only the thirty-eighth week. Occasional cases may occur in which menstruation continues for from two to three months after conception, and the effect of this error upon the obstetric calculation would be under-estimation of the duration of gestation. The latter cases are, however, so rare that miscalculation due to them is quite unimportant from a practical point of view.

Length and Weight as Indications of Maturity at Birth.

Next to the obstetric calculation the length and weight of the infant at birth are regarded as the most important guides. Most lying-in hospitals publish tables of their cases of induction of premature labour for pelvic contraction, in which the length and weight at birth are given along with the calculated duration of gestation. It was, therefore, possible to examine this point pretty fully. Table I. gives the average length and weight, with the extreme variations of both length and weight, of premature babies born at the thirty-sixth, thirty-seventh, and thirty-eighth weeks, in two hospitals.

TABLE I.

Hospital A (London).

	WEIGHT	LENGTH.
38 weeks ..	Average: 5 lb. 10 oz. Limits: 4 lb. 9 oz. to 7·0 lb.	Average: 19 in. Limits: 18 in. to 22 in.
37 weeks ..	Average: 5 lb. 9 oz. Limits: 4 lb. 12 oz. to 6 lb. 3 oz.	Average: 19¼ in. Limits: 19 in. to 21 in.
36 weeks ..	Average: 5 lb. 6 oz. Limits: 4 lb. to 6 lb. 3 oz.	Average: 18¾ in. Limits: 18 in. to 21 in.
Hospital B (Provinces).		
37 weeks ..	Average: 6 lb. 8 oz. Limits: 4 lb. 8 oz. to 8 lb.	This in only given in a few cases.
36 weeks ..	Average: 6 lb. 4 oz. Limits: 4 lb. 12 oz. to 7·0 lb.	

From these figures three points of interest may be gleaned—viz.: (1) Babies born at 36 weeks or at 37 weeks in Hospital B, are on an average nearly a pound heavier than those born in the corresponding week in Hospital A. (2) Babies born prematurely vary in length and weight to as great, or perhaps to a greater, extent than do babies born at term. (3) The relationship between length and weight is subject to very wide variation; premature babies may be long and light, or short and heavy. The most remarkable individual variations noted were the cases of a baby born at the fortieth week measuring 22 in., and weighing 5 lb. 10 oz., and another born at the thirty-sixth week measuring 20 in. and weighing 7 lb., and a third born at the thirty-seventh week weighing 8 lb.

It has been suggested by Frank that the ratio of length in centimetres to weight in grammes is different in mature and premature babies, and that $\frac{w}{e}$ gives a quotient of 50 or less in premature babies, and a quotient of 60 or more in mature babies. I tested this formula over a large number of cases, and did not find it at all reliable.

Necessity of Additional Means of Estimation.

Additional means of estimating the period of development of premature babies are badly needed. A certain amount of work has been carried out by radiologists upon the detection of centres of ossification in the long bones, and the developmental stages at which they appear, or can be recognised by X rays. Meanwhile this work is not sufficiently advanced to be of service.

A promising field, at present unworked, is the cytology of the fœtal blood. The mature infant's blood gives an average of 5½ to 6 million red cells per cubic millimetre; at the thirty-sixth week they may be as high as 8¼ million per cubic millimetre. The proportion of nucleated to non-nucleated red cells is about 1 to 1 at the thirtieth week, while at birth the nucleated cells have practically disappeared, not more than 1000 to 2000 per cubic millimetre being found (Schtchukin[1]). A systematic differential count catheterised himself since then, using a No. 4 catheter. The urine contained a little pus and 1 per cent. sugar. Since June 25th the patient had had continuous pain in the left side, made worse by taking food. The bowels had become confined and the urine had gradually diminished in quantity. The temperature was irregular. A diagnosis of pyonephrosis or possibly a malignant growth was made.

---

[1] Quoted by Feldman: "Principles of Ante-natal and Post-natal Child Physiology."

Operation (July 10th).—Through an oblique lumbar incision, an abscess containing about a pint of slightly offensive pus was opened and drained. The kidney was not distinctly felt, but lay, covered by dense adhesions, behind the cavity. The abscess reached almost to the middle line, upwards to the diaphragm and downwards into the iliac fossa. It was retroperitoneal. A few days later it was found that the amount of urine had slightly increased, but that urine was also escaping through the wound. The pus gradually lessened, but a urinary fistula formed. On Oct. 27th the kidney was removed. At the operation, a hard, elongated body was felt running tranversely across the kidney. Unfortunately, it was impossible to make out its connexions. The kidney was shelled out of a bed of dense adhesions, and the renal pelvis was damaged during the removal of the organ. The kidney was found to be macroscopically normal. There was no more escape of urine from the wound, and the patient is now in good health. The urine is free from sugar.

The third case was one of acute hæmorrhagic pancreatitis in a man aged 54, with fat-necrosis of the omentum and blood-stained fluid in the peritoneal cavity. Free drainage of the retroperitoneal space was provided through an anterior incision, but the patient died 24 hours after operation.

ACUTE PANCREATITIS,

FOLLOWED BY THE DEVELOPMENT OF A PANCREATIC CYST; RECOVERY.

By ROBERT B. CARSLAW, M.A., M.B.,
Ch.M. Glasg.,
VISITING SURGEON, BELLAHOUSTON PENSIONS HOSPITAL;
ASSISTANT SURGEON, VICTORIA INFIRMARY, GLASGOW.

The following case of acute pancreatitis with pancreatic cyst in a woman, aged 27, is of sufficient interest to merit record.

History previous to admission to hospital.—The patient's health up to the birth of a healthy child (10/9/20) had been very good. Two weeks after the birth she suddenly developed severe pain in the upper abdomen and back, this being repeated at irregular intervals during the next five weeks, during which time there was loss of appetite, irregularity of the bowels, and occasional elevation of temperature. On 30/10/20 a tender mass, about the size of a hen's egg, was discovered in the left hypochondrium; and two days later a marked increase in pain, accompanied by almost incessant vomiting.

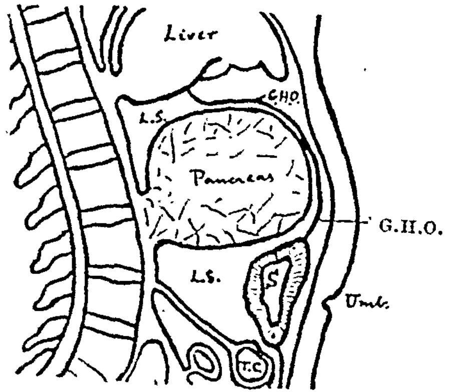

FIG. 1.—Enlarged pancreas, projecting into lesser sac (L.S.), pushing gastro-hepatic omentum (G.H.O.) forwards, stomach (S) and transverse colon (T.C.) pushed downwards.

Condition on admission (3/11/20).—General condition fair, with no emaciation; vomiting frequent, and great pain in upper abdomen and back. The mass, previously noticed in left hypochondrium, had increased in size and was very tender. No jaundice. Urine acid, containing a trace of [illegible] but neither blood nor sugar. Specific gravity 1024.

Operation (4/11/20) (see Fig. 1).—Within 12 hours of admission the general condition became much worse. Vomiting continuous; slight cyanosis; abdomen rapidly becoming greatly distended. The tender mass now filled epigastric and both hypochondriac regions. Abdomen having been opened in middle line, pancreas was found to be enormously enlarged, stomach and transverse colon being displaced downwards. The pancreatic enlargement, which was covered by the gastro-hepatic omentum, was solid, uniform, yellowish in colour, and involved the whole gland. There was marked œdema of the peri-pancreatic tissues, and, in the vicinity of the tail, fat necrosis (confirmed by histological examination) was present. The general peritoneal cavity contained some free fluid, which was not, however, blood-stained. The gall-bladder was distended and contained bile and numerous calculi. Owing to the size of the pancreas the common and pancreatic ducts could not be defined. The gall-stones were removed and the gall-bladder drained.

Progress.—For the next four days the patient was extremely ill, vomiting and hiccough being very persistent and the pulse being often uncountable. From the fifth day there was rapid and uninterrupted improvement, and two weeks after the operation the general condition was very good. By that time, also, the pancreatic swelling had become much reduced in size. Little bile came through the drain during the first two days, but for the next ten days there was an average of 5 oz.

Relapse.—On 1/12/20—that is, four weeks after the operation—there was a recurrence of vomiting, and within the next week a painless swelling appeared which soon filled the epigastric and left hypochondriac regions.

An estimate of the fat in the stools (by Dr. J. Anderson) at this time showed a slight degree of pancreatic insufficiency. The details were, total fat 23·6 per cent., neutral fat 16·0 per cent., fatty acids 7·6 per cent.

Second operation (9/12/20) (see Fig. 2).—Further operative interference being necessary owing to the persistence of the vomiting, the abdomen was again opened. The swelling was found to be a large cyst of the tail of the pancreas, about the size of a child's head. The cyst had pushed the stomach upwards and the transverse colon downwards. It was exposed through the gastro-colic omentum, incised and emptied. It contained a large quantity of slightly turbid, straw-coloured fluid, and a considerable quantity of yellow putty-like material of a tenacious character was adhering to the lining in several places. This was considered to be either secretion which had undergone chemical changes, or necrotic pancreatic tissue. The cyst was unilocular, and the lining was smooth and shiny. The edges of the opening having been stitched to the parietal peritoneum, the cavity was packed with gauze. The fluid was reported by Dr. Anderson to be alkaline, with a slight deposit of red blood corpuscles; on testing its digestive powers no amylase could be demonstrated, but a faint tryptic reaction was obtained.

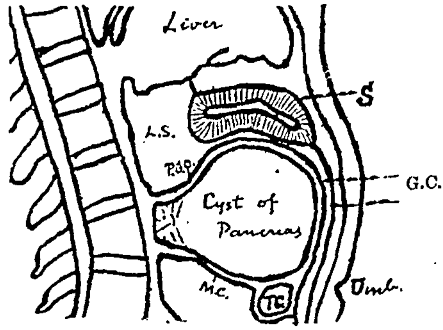

FIG. 2.—Cyst of pancreas, projecting forwards between posterior layer of great omentum (P.G.O.) and transverse mesocolon (M.C.), pushing forwards gastro-colic omentum (G.C.O.), and displacing stomach (S) up and transverse colon (T.C.) down.

Progress.—There was immediate improvement after the operation, the vomiting ceasing and the general condition rapidly becoming very satisfactory. The gauze packing was removed on the fifth day, and the cavity repacked daily thereafter. Two months after the second operation the cavity had become completely obliterated, and the patient has since then been perfectly well.

Remarks.

1. There was evidently at first a subacute inflammation in the tail of the pancreas; later there occurred a sudden spread, and within 12 hours of admission there was a typical acute pancreatitis involving the whole organ.

strictly coördinate with those based on infants known to be premature. Nevertheless the predominant factor in the birth of undersized infants is prematurity, and so far as can be made out from the reports from one-half to two-thirds of the "undersized" babies are premature. It will be seen that the mortality in Classes I. and II. corresponds pretty closely with the figures obtained from cases of induction for pelvic contraction at approximately the same period of gestation.

It is interesting to compare Table III., which represents results obtained during the last five years, with those obtained by Budin at the Clinique Tarnier in Paris in 1895 to 1900, as given in his well-known book "The Nursling." Budin organised a "department for weakling infants"; doubtless not all of the infants were premature, but probably the great majority of them were, and the figures are directly comparable with those just given (Table IV.).

TABLE IV.

Weight.	Percentage mortality.
4½ lb. and over	10·0
3½ to 4½ lb.	13·3
3 lb. to 3½ lb.	60·0
Under 3 lb.	100·0

It will be seen from Table IV. that Budin's results 20 years ago were as good as our own to-day, and *they can only confirm our admiration for the* value of the pioneer work which he carried out in regard to infant management. Probably no clearer or more suggestive thinking as ever been done on this subject.

Problematical Fate of Premature Infants.

A final question arises, which is of immense importance, but to which no answer is at present to be found—viz., "What is the fate of the premature babies after they leave the hospital"? The rule is observed generally in the lying-in hospital that premature babies are not discharged until they are at the time gaining weight; on occasions the mother may refuse to remain or to leave the infant, but, as far as may be, they are kept under observation until they appear to be thriving. Then they pass out of touch with the hospital except for the small proportion which may be passed on to an affiliated infant welfare centre. Lack of coöperation between these centres and the lying-in hospitals is a grievous hindrance to an adequate "follow-up," and is one of the points in inter-hospital coördination which urgently needs attention. Statistics bearing upon the ultimate fate of premature babies would be forthcoming if the hospitals and the centres could work together.

Budin was able to institute a partial follow-up system in Paris for the infants discharged from his clinique; for a portion of their full-time babies, being placed in charge of a wet nurse at the expense of the municipality, could be kept under observation, while those from the "weakling department" were all kept under observation, as far as possible, after leaving the hospital. He was thus able to trace the fate of these infants from 6 to 12 months after their discharge, and he gives the results shown in Table V.

TABLE V.

		Percentage mortality.
Normal babies (all breast-fed)		17·4
Weakling babies (mostly premature)	Breast-fed.. ..	15·0
	Bottle-fed ..	41·0

He believed from these figures that his weakling babies, after discharge from the hospital, had as good a chance of survival as normal babies, *so long as they were breast-fed*, but that if bottle-fed they did very badly, the mortality in the latter case being nearly three times as high as in the former; while in the weakling department of the clinique, all babies were breast-fed, a carefully organised rota of wet nurses being provided for that purpose.

Causes of Mortality of Premature Infants.

Not much information is available from the reports as to the *cause* of this heavy mortality among the premature infants. From the mortality tables it would appear that no other cause of death than "prematurity" was found in 78 per cent. of the cases. It is not stated in how many cases an autopsy was made, and the probability is that in the great majority the diagnosis of the cause of death was clinical only. It is fairly safe to assume that the predominant factor in death from "prematurity" is malnutrition—i.e., failure of the infant to digest or to assimilate the food given. The fatal susceptibility of premature infants to infections of all kinds must not be overlooked; it is due to the fact that their tissues have not yet elaborated a defence against bacterial invasion, and are therefore incapable of "resistance." Breast-fed babies do receive, with the milk of the first 14 days, immunity bodies, which are, no doubt, serviceable for defensive purposes. Bottle-fed premature infants are without defence of any kind, and, of course, fall an easy prey to infection. While in the lying-in hospitals they are fairly free from risk of infection, except that of seasonal catarrh, and the probability is that infections play but a small part in their mortality during the period under consideration.

Importance of Breast-Feeding.

Details of feeding of the premature babies are given in the reports of only one hospital. Here 35·7 per cent. were entirely bottle-fed, while of the mature babies in the same institution only 7 per cent. were entirely bottle-fed. Budin always insisted upon the great importance of breast-feeding for "weaklings," and this point appears to require emphasis at the present time. Mothers of premature babies are doubtless more often unable to nurse than those with mature babies, but in lying-in hospitals it ought to be possible to obtain sufficient breast-milk for the premature babies from the mothers of others, either by wet nursing or by the use of the breast-pump, without depriving other babies of their requirements.

In the case of a small lying-in ward a supply of breast-milk can often be obtained from nursing mothers in the extern maternity, who will usually readily allow their surplus milk to be given to a "sick baby in the hospital." The extern maternity nurse can collect it herself with the breast-pump, and take it to the ward in a previously sterilised bottle. If breast-milk thus obtained is insufficient to supply the total requirements of the premature babies, supplementary feeds can be given, and upon mixed feeding of this description they thrive very much better than upon artificial feeding alone.

It would be exceeding the limits of this note to go further into the question of the management of premature babies, but the *unsatisfactory* results at present obtained should induce all who are concerned with the lying-in hospitals to consider the whole matter afresh.

A NEW METHOD OF EXPOSING THE SUPRA- AND INFRA-CLAVICULAR REGIONS.

BY PROF. N. A. DOBROVOLSKAYA, M.D.,
CONSULTING SURGEON, RUSSIAN HOSPITAL, TEL-EL-KEBIR AND SIDI BISHR, EGYPT.

IN 1916 I described in the *Russky Vrach* a method, worked out on the cadaver, *for reaching the subclavian vessels*. I have now had an opportunity of testing the value of this method on patients, not only for reaching the subclavian but also the axillary vessels and brachial plexus.

The direction of the incision is as follows: It starts in the middle of the neck, between the two heads of the sterno-cleido-mastoid muscle, runs down to the sterno-clavicular joint, which it surrounds in semicircle, and proceeds along the lower border of the clavicle, where it is carried right down to the bone. The periosteum of the inferior and posterior surfaces of the clavicle is to be carefully separated with the man or are of hygienic interest; a little work is done on the diseases of domestic animals, the micro-organisms of milk and its products, plant diseases, and in a few other industrial directions. No one studies, and probably no one is competent to teach, how bacteria in general live and move and have their being. Our bacteriology is technological, and for the greater part medical—an unsatisfactory situation which has followed easily enough from its historical development. As would surely ensue in the case of any branch of knowledge where practical applications outstrip any firm fundamental basis, progress is now hampered by absence of general principles; serology is at a blind end and we have no sound system of distinguishing one species from another owing to neglect of the botanical and zoological aspects of the subject.

It has long been recognised that human anatomy is intelligible only on a foundation of comparative anatomy, the composition of urine only on some knowledge of chemistry in general. The appreciation that pathology and bacteriology cannot get much further on their present sandy and restricted bases is bound to come sooner or later; a careful study of the admirable summary edited by Prof. Marshall will help as a first step to convert those who may still think that human pathological bacteriology is the beginning as well as the end of the subject. Of 992 effective pages, 144 go to morphology, 152 to general physiology; air, water, sewage, and soil have 124, milk and its products 87, the bacteria and protozoa concerned with the diseases of man and domestic animals 245, while the rest is occupied with plant diseases, industrial processes, and so on. The treatment of each subject is, as it must be in a single volume, short and summary, but it is enough to shake the faith that our previous manuals contain all that we need know about bacteria. We are not aware of any other book which gives such an illuminating survey of the manifold activities of micro-organisms. Without any hesitation it can be said that every serious student and every laboratory ought to have a copy—which is the easier because, as things go nowadays, it is a very good guinea's worth of quantity. Many readers will probably complain that it does not say enough about the particular topic which interests them, but in a book of this size that cannot be helped; the same objection has, after all, been made to the Encyclopædia Britannica.

The book is handy in form, compact, and closely but clearly printed (in America), and the present edition has been expanded and rearranged in many places.

INSANITY AND MENTAL DEFICIENCY IN RELATION TO LEGAL RESPONSIBILITY.

A Study in Psychological Jurisprudence. By WILLIAM G. H. COOK, LL.D. Lond., of the Middle Temple, Barrister-at-Law. London: George Routledge and Sons, Ltd.: New York: E. P. Dutton and Co. 1921. Pp. 216. 10*s.* 6*d.*

"Dr. Cook has the good fortune to treat of a subject rarely dealt with as a whole." So wrote Sir John Macdonell, a learned lawyer, who has since died, in a foreword contributed to Dr. Cook's thesis for the doctorate of laws in the University of London, now published in book form. Sir John Macdonell's observation was apt, for we know of no similar work of so exhaustive a character, and Dr. Cook is to be congratulated upon his choice of an important but obscure subject in medical jurisprudence. It is in no way to his discredit as a lawyer if, having been able to assemble a large number of cases for discussion of the principles and rulings involved, with occasional references to the laws of foreign countries, he leaves us certain of little except of the uncertainty of the law with regard to the civil rights and liabilities of the mentally affected. Presumably the law would have been richer in decisions if insane persons, when financially worth proceeding against in respect of their [illegible] or their torts, were not, as a rule, too well [illegible] er to enter into the former or to commit the latter. However, in the cases that he cites, Dr. Cook finds plenty of material for criticism and for suggestion.

Medical science has made progress in its understanding of the problems presented by the varying phases of mental unsoundness, and is apt to find the law unprogressive and unsympathetic in dealing therewith. Dr. Cook's point of view in criticism is that of the medical expert rather than of the lawyer, where the two are not in accord, and the fact that he criticises and suggests as well as records precedents gives a readable quality to his work which the legal treatise often lacks. The occasions which raise questions of mental capacity in civil courts are not, of course, confined to actions arising out of torts or out of ordinary commercial contracts. They may arise also out of the desire to obtain a decree of nullity of marriage, or in reply to a petition for divorce, and perhaps they are discussed most frequently in connexion with the alleged incapacity of a testator.

Those who are interested in any aspects of these complicated questions will find much to interest them in the perusal of Dr. Cook's monograph.

ANDREAS VESALIUS.

Six Anatomical Plates of the Year 1538. Edited and presented by MORIZ HOLL (Graz) and KARL SUDHOFF (Leipzig) to the eighty-sixth meeting of German Philosophers and Physicians at the Festival of the 400th Anniversary of the Birth of Vesalius. Leipzig: Johann Ambrosius Barth. 1921. Pp. 12 and plates. M.60.

THIS reproduction of six anatomical plates designed nearly 400 years ago by Andreas Vesalius serves to show how advanced Vesalius was as an anatomist, although the great secret of the circulation was hidden from him. The first plate illustrates the portal vein; the second the distribution of the venæ cavæ; the third the great arterial system consisting, according to Vesalius, of 147 vessels which convey the "vital spirit" from the left side of the heart to the whole body; the fourth plate is a graphic representation of the skeleton from the front; the fifth is the skeleton seen sideways; and the sixth from behind.

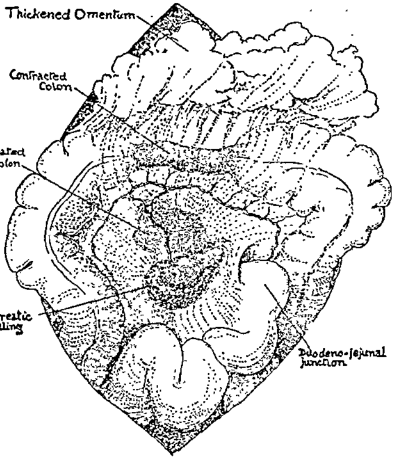
These old drawings have all the force and grace of those dances of death which were popular decoration in the Middle Ages. Skeletons as depicted in a nineteenth or twentieth century text-book are accurate collections of dry bones held together by wire; the skeletons of Vesalius have expression, and as they beckon, admonish, and encourage with gesture they remind us of the wall paintings in churchyards for which the word *macabre* has been coined.

THE CARE OF EYE CASES.

A Manual for the Nurse, Practitioner, and Student. By ROBERT HENRY ELLIOT, M.D., B.S. Lond., Sc.D. Edin., F.R.C.S. Eng., Lieut.-Colonel I.M.S. (Ret.), Lecturer in Ophthalmology, London School of Tropical Medicine. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 172. 12*s.* 6*d.*

A MEDICAL author can essay no more difficult task than that of writing a book for nurses. The middle course between inadequate simplicity on the one hand and overabundant and perplexing detail on the other is difficult to achieve and still more difficult to maintain. The intelligent nurse learns the actual practice of nursing ophthalmic cases in the wards under a sister's tuition, but she soon realises that there is a definite limit to the information available from this source. Questions regarding the uses of instruments, the theory underlying procedure, methods of examination, and the mysteries of disease, gain no satisfactory answers, and Colonel Elliot's desire to supply a source of reliable information is a praiseworthy one. Frankly, however, we do not think he has succeeded. He has covered a great deal of ground, and one or two of his chapters are excellent. The majority, however, especially those of Part II. on diseases, err on the side of simplicity and convey hardly more detail than the average chest showed nothing unusual. The abdomen moved fairly well except in the upper part, where there was a prominence, most marked half way between xiphisternum and umbilicus and slightly to the left of the middle line. Palpation caused no pain except over the swelling, which was extremely tender to the lightest touch and conveyed an elastic sensation to the hand. The limits of the swelling could not be precisely defined, fading off gradually below and on either side, and passing above into the liver dullness. In the series of analysed cases there are three in which the liver dullness was found to be diminished. In this case the liver dullness was normal in extent. The swelling was rather tympanitic on percussion. No friction sound was heard over it. The rest of the abdomen was slightly distended and dull in the flanks.

Operation.—The abdomen was opened over the epigastric swelling. A quantity of slightly blood-stained fluid escaped, perhaps three pints. The great omentum was found to be much thickened and rolled upwards towards the stomach. Nothing unusual was found at the examination of the gall-bladder or bile-ducts. The stomach, empty and natural in size and appearance, lay in front of part of the swelling described above, the greater part of the prominence being accounted for by the massing of infiltrated great omentum along the greater curvature of the stomach. The lesser sac probably contained half a pint of fluid. The pancreas was most easily reached from below the transverse mesocolon. In this region, just above and to the right of the duodeno-jejunal flexure, a dull-red swelling was found lying behind the parietal peritoneum and extending forwards for an inch or more between the layers of the transverse mesocolon. Opposite this infiltrated area the transverse colon was contracted and discoloured, as indicated in the illustration. The appearance of the affected segment was in striking contrast to that of the bowel above and below. For a distance of 3 inches the colon was so much contracted that its lumen must have been almost occluded. Yet the cæcum, ascending colon, and hepatic flexure were flaccid, but the small intestine contained a considerable quantity of gas. The contracted part of the transverse colon was marked off sharply at both ends. Its peritoneal covering was intact but had lost its glossy appearance. The colour was a dark mahogany, the wall thick and rigid. The pancreatic swelling was exposed and incised after the peritoneal cavity had been protected by gauze packing. A little dark-red somewhat offensive fluid escaped; also a few fragments of friable material, thought to be broken-down pancreatic tissue. The finger was now passed into the retro-peritoneal space and the pancreas examined. The head of the gland felt fairly firm, the body and tail soft and friable. The discharge from the cavity was mopped out, a large drainage-tube inserted, the gauze packing removed, and the abdomen partly closed. Nothing was done to the contracted colon, in order to avoid prolonging the operation. On May 13th the patient's hands became extremely cold and her face rather cyanosed. Her mind was quite clear, and she could answer questions. The radial pulse could no longer be easily counted. For some days her condition remained the same. She had to be catheterised morning and evening. The bowels were kept open with difficulty. The vomiting lessened, but the abdomen was still distended and tender. Contrary to expectation, improvement gradually set in. For nearly three weeks after the operation much foul brownish fluid came through the tube, causing excoriation of the surrounding skin. This was treated by the application of picric acid ointment. On May 29th the escaping fluid was still rather offensive, but we collected it in a vessel for daily examination. On June 21st the discharge suddenly and finally ceased. The patient left the hospital on the same day, weak and pale, but well as far as the abdomen was concerned. When she reported herself early in August her general condition was much better, but it was found that a hard mass the size of a tennis ball had appeared behind the centre of the scar. It was well defined, freely movable in all directions, and neither tender nor painful. There was also a diffuse swelling in the left iliac region, from which a little pus was removed with an exploring syringe. The patient was advised to come into the hospital again, but she refused. She was seen a few weeks later, and, curiously enough, both epigastric and lumbar swelling had entirely disappeared, and she looked and felt perfectly well.



Appearance of the transverse colon, transverse meso-colon, and pancreatic swelling after drawing the great *omentum upwards.*

The fæces were always brown, doughy, and offensive. A little fat was found in them during the first fortnight, but none after May 28th. The urine was always free from sugar.

Observations (made by F. H.) upon the Pancreatic Fluid Collected from the Fistula.

On May 30th the amount of pancreatic fluid secreted in 24 hours was 450 c.cm. This was about the usual daily quantity. On June 1st, between 11.20 A.M. and 12.20 P.M. (one hour before the mid-day meal), the amount secreted was 25 c.cm. At 12.20 a meal consisting of soup, a little meat, potato, and green vegetables was given. From 12.20 to 1.20 there was no secretion at all. From 1.20 to 2.20 only a few drops were collected. From 2.20 to 3.20 the amount secreted was 55 c.cm.

Disturbance of gastric digestion also influenced the quantity of the pancreatic secretion. On June 8th, for instance, the patient was not feeling well and was sick after a dinner consisting of meat and vegetables. The secretion between 8.30 A.M. and 5.30 P.M. on that day amounted to only 30 c.cm. As the gastric derangement passed off the secretion gradually increased again. On June 12th it was 300 c.cm. for the 24 hours. The presence of trypsin, amylopsin, and steapsin was proved by the effect of the pancreatic fluid on boiled white of egg, boiled starch, and olive oil. The fluid was never quite free from offensive odour. It contained a few pus cells and was soapy to the touch.

There are several noteworthy points in this case:—(1) The epigastric swelling was caused not so much by the pancreas as by the rolled-up and thickened omentum. (2) The remarkable condition of the transverse colon. The infiltration of the transverse meso-colon with dark red fluid did not actually reach as far as the colon; the middle colic artery ran through this infiltrated area towards the contracted segment of colon, the vessel and its accompanying nerves being doubtless influenced by the highly irritating fluid. The colon must have resumed its normal appearance and function soon after the operation. (3) The suddenness with which the pancreatic discharge ceased. (4) The absence of pancreatic secretion during gastric digestion and the re-establishment of the flow while food passed through the duodenum.

Besides this case there have been only two other cases of acute pancreatitis under the writer's care during the past seven years.

In the following there may be some doubt as to the correctness of the diagnosis.

CASE 2.—Mr. N. S., aged 50, gave a history of sudden severe pain beginning in the epigastrium and travelling through the left hypochondrium into the back. This occurred on June 25th, 1920, but he did not come under observation till July 7th, when the writer saw him in consultation with Dr. F. Parkes Weber, who has kindly consented to the publication of this note. When the patient was admitted on June 7th, there was a large globular swelling in the left lumbar region reaching from under cover of the ribs to the upper part of the left iliac fossa. The swelling was tender, dull on percussion, crossed by the left part of the transverse colon above, fixed, and reaching back into the loin. The patient gave a history of gonorrhœa in 1895, followed by the development of a stricture. He had

CONTROL OF MEASLES IN LONDON.

THE resolutions of the conference of London borough councils which was convened in February last have recently been under consideration by the Public Health Committee of the Council, and the recommendations which the committee is now prepared to make were this week presented to the Council for ratification. The conference of borough councils was invited to consider (1) proposals for further legislation, and (2) proposals for making more effective the existing powers of the Council and the local sanitary authorities. No proposals were made for further legislation, but on the second point of reference the conference adopted the following resolution :—

> "That for the better control of measles in the county of London there should be the fullest measure of coördination between the central and local authorities and other agencies concerned in the care of children : and it is desirable that : (i) Every effort should be made through the school organisation to obtain the earliest possible information with regard to the reasons for absence from school of children, especially those attending infants' departments, and that the fact of the existence of measles in the homes of the children should be communicated at once to the local medical officer of health. (ii) Steps should be taken, if possible, to ensure that parents and guardians of children liable to attend school should notify the head teacher of the school within 48 hours when a child is kept away from school on account of ill-health, stating the apparent nature of the illness or indisposition from which the child is suffering. (iii) Every possible effort should be made to develop the provision of nursing assistance in the case of measles, and that the authorities of all hospitals and dispensaries and private practitioners should be made aware of the facilities that exist for obtaining nursing assistance in the case of measles, and that forms should be supplied to them upon which application could be made for nursing treatment in suitable cases."

In order to meet the proposal contained in paragraph (1) of the resolution the Public Health Committee of the London County Council is prepared to take steps to issue to school teachers and attendance officers a general instruction to acquaint the borough medical officer at once of all detected cases of measles, particularly where young children under school age are affected and where home conditions are unsatisfactory. When there are indications, during times of normal prevalence of measles, that the disease is increasing in any particular school or group of schools the committee is also prepared to put into operation the scheme applied successfully in 1913. This scheme involved special arrangements under which head mistresses of schools in affected areas informed the divisional superintendent of all absentees every Tuesday morning, and cases of measles were at once reported to the borough medical officer. It is also proposed that when measles tends to become epidemic, when the number of reported cases from London schools approaches 1000 weekly, to apply the scheme experimentally put into force in 1920, entailing close cooperation between school nurses, the attendance officers, and the staffs of the local sanitary authorities.

Regarding notification by parents and guardians of absence due to illness of any sort, the Public Health Committee has been advised that it is not within the power of the Council to make a by-law requiring parents to make such notifications. The Education Committee however, is considering whether anything further can be done to secure the fuller coöperation of parents and guardians.

The recommendation of the conference that every possible effort should be made to develop the provision of nursing assistance is a matter in which the London County Council has no responsibility. This work in London devolves entirely on the City Corporation and the borough councils. It appears, however, that the work of the borough councils is impeded, owing to imperfect appreciation of existing nursing facilities, not only by parents but by those engaged in medical work. The Public Health Committee therefore pro- [illegible] to approval by the borough councils, to circularise hospitals, dispensary authorities, and private practitioners throughout London, directing their attention to available nursing facilities.

Compulsory Notification.

With reference to a second resolution passed by the conference : "That this conference is of opinion that the notification of measles by the medical profession is necessary for the following purposes—viz. : (*a*) To secure the prompt segregation of susceptible contacts attending the public elementary schools ; and (*b*) to render efficient any provision of nursing aid by the local authority," the Public Health Committee of the Council believes that more complete information with regard to new cases of measles is obtained through the school organisation than through compulsory notification. In a large proportion of cases a medical man is not called in at any stage of the disease. The committee agrees with the county medical officer that the detection and reporting by the school organisation of cases of measles gives a more complete result than would be attainable by compulsory notification, and that the public money that would be needed for compulsory notification could be more usefully spent on additional nurses, health visitors, or after-care of patients.

In response to an invitation from the Ministry of Health to express the views of the London County Council on a proposal by certain borough councils that measles should again be made notifiable, the following resolution was submitted by the Public Health Committee for consideration by the council :—

> (*a*) That if so desired by the metropolitan borough councils the Council is prepared to send to the authorities of all hospitals and general medical dispensaries and to all private medical practitioners in London a communication, in a form satisfactory to the borough councils, directing attention to the facilities available through the public health services for the nursing of cases of measles in London.
>
> (*b*) That the Council considers that until more experience has been gained of improved arrangements for the detection and notification of measles through the school organisation, it would not be desirable to adopt the proposal to make measles compulsorily notifiable by medical practitioners throughout London ; and that a representation to this effect be made to the Minister of Health.

After two members of the Council had spoken on the resolution, the debate was adjourned till the next meeting of the Council.

INTERNATIONAL CONFERENCE ON TUBERCULOSIS.

THIS Conference will be held at the Institute of Civil Engineers, Westminster, from July 26th to 28th, and over 100 delegates from other countries have already announced their intention of being present. Mr. Léon Bourgeois, President of the French Senate, will be in the chair, and among those who have accepted invitations are Sir George Newman, Sir Robert Philip (President-Elect), Sir Humphry Rolleston, Hon. Sir Arthur Stanley, Sir StClair Thomson, Prof. Sir German Sims Woodhead, Mr. Woolcombe, and Sir William Younger, Great Britain ; Prof. Calmette, Assistant Director of the Pasteur Institute, Dr. Armand Delille, Grancher Institute, and Prof. Léon Bernard, Hon. Secretary International Union, France ; Colonel Bushnell, head of Medical Department of the U.S.A. Army ; Dr. Hatfield, Managing Director of the National Association of the U.S.A. ; Dr. Linsley Williams, Dr. H. Landis, Miss Mary Gardner, Dr. Gerald Webb, and Dr. Charles Minor, United States ; Prof. Ascoli and Prof. Pio Foa, Italy ; Prof. Harbitz, one of the leading authorities in Europe, Norway ; H. E. the Chamberlain to the King, Sweden ; Prof. Nolen, Holland ; Dr. Dewez, President of the Belgian National League against Tuberculosis, and Dr. Gaston Grégoire, Governor of Liége, Belgium ; Dr. Siah, China ; and Prof. Winslow, League of Red Cross Societies. Delegates are also coming from Australia, Canada, South Africa, India, New Zealand, Denmark, Czecho-Slovakia, Greece, Argentina, Brazil, Spain, Roumania, the Republic of Colombia, Guatemala, Luxemburg, Haiti, Monaco, and Panama. Lord Curzon and Sir Alfred Mond, Minister of Health, will welcome the Conference on behalf of the Government.

2. The relief of the symptoms which followed the removal of the biliary calculi and drainage of the gall-bladder is difficult to explain in the absence of jaundice.

3. The vomiting which recurred on the development of the cyst was clearly due to pressure on, and displacement of, the stomach and duodenum and the consequent interference with their mechanical function. It was remarkable that, notwithstanding the size of the swelling, all other symptoms were absent, there was no pain, no jaundice, no glycosuria, no steatorrhœa, merely a slight degree of pancreatic insufficiency.

4. The chief point of interest was the formation of a large cyst within one month of the onset of the acute pancreatitis. This was not due, as is usually the case, to a chronic indurative pancreatitis, but was caused by the blocking of ducts, either by secretion which had become tenacious, or by necrotic pancreatic tissue. It is significant that it occurred in the tail, the part of the gland which was earliest and most acutely affected. The remainder of the gland recovered.

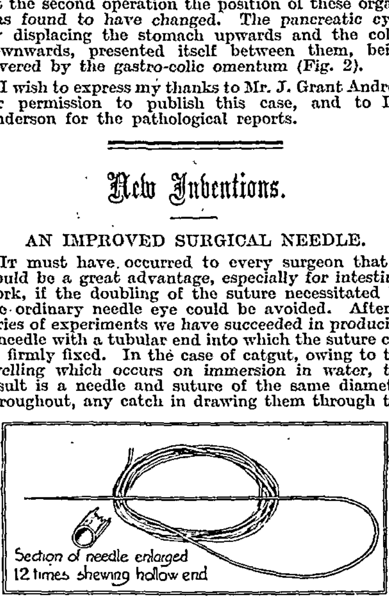
5. A further point of interest is the change in the relative position of the stomach, transverse colon, and pancreas. At the first operation it was noted that the enlarged pancreas had pushed the stomach and colon downwards, and was showing above the former, being covered by the gastro-hepatic omentum (Fig. 1). At the second operation the position of these organs was found to have changed. The pancreatic cyst, by displacing the stomach upwards and the colon downwards, presented itself between them, being covered by the gastro-colic omentum (Fig. 2).

I wish to express my thanks to Mr. J. Grant Andrew for permission to publish this case, and to Dr. Anderson for the pathological reports.

New Inventions.

AN IMPROVED SURGICAL NEEDLE.

It must have occurred to every surgeon that it would be a great advantage, especially for intestinal work, if the doubling of the suture necessitated by the ordinary needle eye could be avoided. After a series of experiments we have succeeded in producing a needle with a tubular end into which the suture can be firmly fixed. In the case of catgut, owing to the swelling which occurs on immersion in water, the result is a needle and suture of the same diameter throughout, any catch in drawing them through the tissues is entirely avoided, and the performance of delicate intestinal suturing is greatly facilitated. The needle is being manufactured for us by Messrs. Charles Spencer, of Redditch, who will shortly be able to supply it in every form, straight or curved, round or cutting, and in every size. Threaded with "London Hospital" catgut, packed sterile in tubes and ready for immediate use, they can be obtained from Messrs. Allen and Hanburys, the sole distributing agents for the hospital.



H. S. SOUTTAR, F.R.C.S.,
Director of the Surgical Unit, London Hospital.

Reviews and Notices of Books.

SQUINT.

Its Causes, Pathology, and Treatment. Fifth Edition. By CLAUD WORTH, F.R.C.S. London: Baillière, Tindall and Cox. With 42 figures in the text. 1921. Pp. 242. 12*s.* 6*d.*

THIS book is substantially the same as when it was first published in 1903. Its great value lies in the lucidity with which is explained the ordinary concomitant squint of children, a subject which formerly was commonly misunderstood. Early attempts to account for the condition by supposed anomalies in the eye muscles themselves were seen to be unsatisfactory, but the theory of Donders held the field for many years. This theory is based on the fact that the accommodation of the eyes for near objects is generally associated with convergence of the visual axes. In cases where hypermetropia exists the extra accommodation rendered necessary is apt, according to this theory, to involve such an extra amount of convergence that an internal squint may occur. That Donders' theory, however valuable as a partial explanation of the phenomenon of squint, was not by itself sufficient had long been felt by ophthalmologists, but no one had put the matter so clearly until the publication of this book. Since a great many children who suffer from convergent squint have no more than the average amount of hypermetropia, the latter, while doubtless a contributing cause in many cases, cannot be the essential cause of the condition. The real cause, Mr. Worth maintains, is to be found in defect of the faculty of fusing the two slightly varying images formed on the two retinæ, a faculty normally developed during the first few months of life. In its absence various conditions, one of which is the presence of hypermetropia, may determine the onset of squint. When this occurs it only rarely happens that any diplopia is noticed, the reason being that the image formed in the squinting eye is suppressed. From suppression of the image amblyopia in the squinting eye arises, a condition that easily becomes permanent unless combated by timely treatment. Nowhere, we believe, is all this so clearly set forth as in this book.

The non-operative treatment is very satisfactorily dealt with. In the case of young children the most urgent necessity is to combat the onset of amblyopia by occlusion of the fixing eye. In comparison with this first essential the education of the fusion faculty and of binocular vision is of secondary importance. Of the many devices which have been invented for the latter purpose Worth's amblyoscope is probably the best, provided that it is practicable for the surgeon to devote the necessary time to the education of the patient. With regard to the operative treatment of squint the varieties in the method of advancement practised by different operators are manifold, and the particular method described in this book will be considered unnecessarily complicated by some who are in the habit of obtaining excellent results from simpler ones. As to the question of tenotomy versus advancement there is also a variety of opinions, but we believe that the best of these supports Mr. Worth's conclusion in favour of advancement as the most satisfactory and the safest procedure. He goes so far as to reject tenotomy altogether on the ground that one never can tell just how great the ultimate effect will be.

MICROBIOLOGY.

Third Edition. By 25 Contributors. Edited by C. E. MARSHALL, Professor of Microbiology in the Massachusetts Agricultural College. London: J. and A. Churchill. 1921. Pp. 1013. 21*s.*

THERE is at present in this country no organisation for the study of bacteriology as such. At least nine-tenths of the energy and time that is put into its prosecution is devoted to those organisms which are known or suspected to be of pathogenic importance to vitro the presence of entero-kinase in the intestinal secretion of our patient.

We then chloroformed a dog, eight kilogrammes in weight, and during the period of digestion injected into the pancreatic duct 2 c.c. of intestinal secretion collected from the patient. The animal was killed three days later, and at the autopsy we found typical hæmorrhagic pancreatitis with fat-necrosis.

We can thus surmise, alongside of a biliary origin, the possibility of an intestinal origin of pancreatitis, in support of which conception we may quote the recent experiments of Gosset, J. Camus, and Monod,[4] who, when operating with the view of establishing permanent biliary fistulæ, noted the accidental occurrence of hæmorrhagic peritonitis. In their experiments the bile drained away, and was not able to be held responsible for the conditions which were due to the duodenal secretion.

3. *The Rôle of the Pancreatic Secretions in the Production of Pancreatitis.*

In a thesis, Paul Carnot[5] insisted at length on the possibility of reproducing the lesions of hæmorrhagic pancreatitis by injections into the gland of trypsin, of pancreatic extract, and of papaine, and experimental researches have led him to affirm that hæmorrhagic pancreatitis is the result of auto-digestion.

To these three categories of experiments may be added others which admit the conception of—

4. *A Multiplicity of Factors in the Production of the Pathological Condition.*

Calcium Salts.—Our experiments have shown[6] that the injections into the pancreatic duct of a sterilised solution of chloride of calcium will result in a pancreatitis remarkable for its intensity, and, secondly, will produce as a complication a pseudo-cystic cavity in the substance of the gland. We have made three researches along this line and three times we obtained hæmorrhagic peritonitis with fat-necrosis, while once we found on the surface of the body of the pancreas a cavity of the size of a large nut reproducing the type of a spurious cyst of the pancreas in its earliest stage of formation.

Pilocarpin.—We have repeated with identical results the experiments of Opie, making, that is, an intravenous injection of pilocarpin after ligature of the pancreatic duct, when the animal developed hæmorrhagic pancreatitis and fat-necrosis.

Traumatism.—Experimental injuries to the pancreas of a dog with the duct ligatured in the process of digestion resulted in hæmorrhagic pancreatitis, which did not occur in the fasting animal.

Leucocytes, Microbes, Toxins. — The injection of leucocytes, without microbes, into the pancreatic duct of a dog has been followed by pancreatitis and fat-necrosis. The injection of coli bacilli and of diphtheria toxin has been found by Paul Carnot to produce the same in typical form.

5. *The Interpretation of the Researches.*

From the preceding facts we may conclude, as Carnot has premised, that the condition of hæmorrhagic pancreatitis with fat-necrosis is an auto-digestion. Its pure form presented appears to us to be a process of fermentation, allied to the activation of pancreatic ferments, trypsin, and lipin. Normally in the gland and in the pancreatic duct system the ferments are inactive in the condition of pro-ferments; the trypsin in particular exists as a pro-trypsin, or trypsinogen. It can be activated in situ by the entero-kinase (duodenal reflex), by a cyto-kinase derived from pancreatic tissues injured by traumatism, by calcium salts experimentally injected; by a leuko-kinase or bacterio-kinase, in the case of an ascending infection in septicæmia.

When activated the trypsin damages the vessels and the cells and causes the hæmorrhage. On the other hand, the lipin attacks the fats and saponification results, with evolution of fatty acids, and soaps, and the appearance of fat-necrosis. It can be imagined that the pancreatic juice will act the more powerfully as its excretion becomes more difficult. As to the mode of action of the bile, this can be interpreted in several ways. The bile reinforces the pancreatic lipase (Claude Bernard, Dastre) and the fat-necrosis becomes intense; but if we attempt to incriminate the bile in its isolated state, and not the intermixture of bile and intestinal secretion—i.e., the duodenal content, how can we explain the activation of the trypsinogen? Either there is direct activation of the pro-trypsin by the bile, or the bile damages the pancreatic cells with the production of cyto-kinase, and thus indirect activation of trypsinogen.

A last question arises, What is the mechanism by which either the bile or the intestinal secretion reaches the intra-pancreatic secretory system? The possibility of a direct reflux of the bile into the canal of Wirsung is admissible while dealing with man—a calculus in the ampoule de Vater, hypertension in the biliary ducts, or spasm of the sphincte of Oddi.

Recently, in experiments full of interest, E. Archibald and Bron[1] have produced hæmorrhagic pancreatitis in the cat by a reflux of the bile of the common bile-duct into the pancreatic duct, or by simple elevation of the pressure in the biliary system, or by associating with this elevation of pressure a spasm of the sphincter of Oddi secured by cauterising the duodenal orifice of the canal of Wirsung with a solution of hydrochloric acid after duodenostomy.

In the case, as of man, where the pancreatitis manifests itself outside lesions of the biliary tracts, it may be the result of a reflux into the pancreatic system of the duodenal contents. This reflux, difficult in the main duct which is protected normally by the anatomical structure of the ampoule de Vater and the sphincter of Oddi, could perhaps be possible in the accessory canal of Santorini, which, according to the researches of Opie, discharges in a tenth of the subjects the principal duty of excretion. The orifice of such an abnormal canal is, perhaps, says Opie, incapable of preventing regurgitation of the intestinal contents when the pressure in the duodenum is increased by vomiting, by intestinal spasm, or by occlusion at the duodeno-jejunal angle, or in the third portion of the duodenum.

Siedel (1910) no doubt recognised the condition of hæmorrhagic pancreatitis as following on duodenal stasis. One of us has experimented in this direction and obtained on the dog a typical hæmorrhagic pancreatitis while operating in the following manner.[8] In the first instance, exclusion of the pylorus and posterior gastro-entero-anastomosis. A month and a half later, in the second instance, stricture of the terminal portion of the duodenum by means of a cord strongly tied on the duodenum, at two fingers-breadth above the mouth of the jejunum. The third day after the operation the animal died from typical hæmorrhagic pancreatitis. It is true that the conditions of this experiment are different from those which could occur in man. However, it seems to us permissible to think that in certain abnormal or pathological states of the anastomosis of Wirsung or of the sphincter condition of Oddi, hyper-pressure in the duodenun caused by vomiting or by exaggerated contractions in duodenal occlusion could bring about pancreatitis by reflux of duodenal contents into the pancreatic canal.

popular medical dictionary. Part I. is mostly concerned with nursing proper, but contains a chapter on the anatomy of the eye, and one on special methods of ophthalmic diagnosis, wherein various instruments, such as the binocular loupe, the transilluminator, the perimeter, Bjerrum's screen, tonometer, and others are briefly described. Illustrations from trade catalogues are given of almost all. The chapters on nursing are the best, but they hardly bear comparison with Mr. Sydney Stephenson's manual on the same subject, though perhaps more up to date. A whole chapter is devoted to subconjunctival injections. In an appendix a list of instruments for various operations is given, also illustrations of most instruments in ordinary use.

Colonel Elliot has, we think, attempted to combine in one a book of reference and a manual of nursing. The result is not satisfactory. Both are needed, but they should be kept separate and distinct. His book, however, contains many good things, and in the absence of a better should without question be recommended to the ophthalmic nurse.

BOTANY.

An Introduction to the Structure and Reproduction of Plants. By F. E. FRITCH, D.Sc., Ph.D., F.L.S., and E. J. SALISBURY, D.Sc., F.L.S. London: G. Bell and Sons, Ltd. 1920. Pp. viii. + 458. 15*s.*

THIS book is intended as a sequel to the "Introduction to the Study of Plants" by the same authors. The two volumes form together a very complete introductory course in botany; and the later one will also prove valuable by itself, since it treats of anatomy rather more fully, and more from the physiological standpoint, than has been usual in handbooks of an intermediate standard. In the first part of the book the structure of the plant cell, its methods of division, and its contents are described; then follow chapters on the structure of the various plant organs and anatomy related to habitat. The second part gives a general survey of the great groups of the vegetable kingdom and closes with a useful chapter on heredity and evolution. The illustrations are numerous and are arranged in 230 figures, about two-thirds of which are original. These are well drawn, and though finished in a slightly diagrammatic style that makes them particularly useful to students, they are not untrue to nature. In order to give the reader a better general description of each group of plants as a whole, the study of isolated types is abandoned. Numerous examples are introduced and thus the range of form and reproductive methods characteristic of each group are well illustrated. The book will prove of great value to the general botanical student and can be warmly recommended to those preparing for the Intermediate Science and First Medical Examinations.

JOURNALS.

Journal of Anatomy. Vol. LV., Parts 2 and 3. January and April, 1921. Cambridge University Press. Pp. 79–217, with 10 plates. 20*s.*—Dr. E. A. Linell opens this number with an account of variabilities in distribution of nerves in the upper limb. This record of painstaking observation, of great clinical interest, is not of a nature to admit of abstraction, but will form a source of information for anatomical textbooks and for surgeons.—Miss I. C. Mann, writing on the development of the fissural region in the eyes of chicks and some mammals, calls attention, among other things, to the eversion of the non-pigmented layer of the optic cup along the lips of the fissure. This is a definite sauropsidan feature, and leads to the appearance of the "cauda" on the surface of the eye in this class, but it is also definitely seen in mammals at early stages. She also describes the pecten as ectodermal in origin, not mesodermal as usually described.—Mr. W. B. Primrose deals with the evolution of the vertebrate endoskeleton, bringing it through hydroskeletal, hydrostatic, sclerotomic, and neural stages to the final neuro-muscular skeleton of the vertebrate. The views he promulgates are of interest in relation to certain ontogenetic details such as the nature of the changes occurring in formation of the notochord from cells. The paper is one of great interest; the relation between segmentation and excretion, however, calls for consideration.—Prof. L. Bolk, of Amsterdam, contributes two important "odontological essays." The first deals with the development of the palate and alveolar ridge in man, in which he shows that the alveolar ridge is a new formation, not made from the outer border of the secondary palate. This has, of course, been known to English anatomists for a considerable time, those who had worked in this region being well aware that the so-called "alveolar ridge" of the earlier stages is taken into the palate, with secondary formation of a true alveolar ridge, but it is well that the matter should be definitely pushed home in detail. Prof. Bolk incidentally points out with justice that there is no heaping up of epithelium along the jaw such as German writers distinguish as the "Zahnwall." The second essay, on the development of the enamel-germ, is much longer, and is filled with observational details of these organs in many varieties of animals, including man. The general presence of what he terms an "enamel-niche" and "enamel-canal" makes a new feature brought forward by the writer of the essay and not described previously. It has been customary to describe an area of stellate change in the cells of the organ, but Prof. Bolk shows that there are double areas in mammalian teeth, lingual and labial; as there are single areas in reptilian organs, the phylogenetic interest becomes apparent. Morphologists will look forward with interest to the appearance of the further essays of this series.—Prof. E. Fawcett adds to his work on the chondrocranium with a careful and detailed account of the primordial cranium in 12 mm. and 17 mm. embryos of *Tatusia novemcincta*, the paper being furnished with several beautiful plates. Among many interesting features, it may be pointed out that these embryos show clearly that the interorbito-nasal cartilage (septum) is probably not to be looked on as a trabecular prolongation; the appearance of the maxilla is very suggestive of a double centre of ossification; the posterior paraseptal cartilages develop independently of the hinder part of the floor of the nasal capsule. This is a most important contribution to our knowledge of mammalian crania.

Japan Medical World. Vol. I., No. 1. May 15th.—Although many adjustments may yet be required before East and West can meet in full communion of spirit, medicine, which is international in its outlook and bearings, has already gone far to this end. Japan has rapidly risen from oriental mediævalism and while some 50 years ago she was simply receptive of Western culture she is now adding her share to the common stock of knowledge which makes for progress, particularly so with regard to medicine. This is exemplified by a new monthly journal published in English, entitled the *Japan Medical World*, which deals with medicine, surgery, and collateral sciences. The editor is Dr. K. Miyajima and the journal is published by the Nippon-No-Ikai Sha, at Kanda. The first number includes original articles, a review of Japanese medical literature, a report of the proceedings of medical societies, and medical news. The original articles are: A New View of the Intermediate Metabolism (Y. Kotake, Osaka); On the Diuretic Principle of the *Myrica Alba* (K. Abe and H. Takahara, Tokyo); Experiments on the Filtration of Water Containing Encapsulated Larvæ of *Clonorchis Sinensis* (M. Muto, Nagoya); On the Influence of the Amino Acids for the Growth of Gonococcus and other Cocci (R. Kobayashi and E. Nishikawa, Tokyo); On the Structure of the Cell Nucleus (O. Tamura, Okayama); and On the Development of the *Paragonimus Westermanni* and its Prevention (S. Kobayashi, Korea). The journal consists of 48 pages, and is published at a yearly subscription of 12 yen, post free, or $6 for foreign subscribers.

glands and the pancreas have been recently sought for (R. Pemberton and J. E. Sweet, E. Gley, Lusk, Graham and Riche, F. C. Mann and Della Drips).

First dog, weighing 10 kg., injection of 1 mg. adrenalin.

Blood Sugar.

	Before.	After pancreas was extirpated.
Before injection ..	0·65 g. ..	3·20 g.
After 10 min.	0·80 „ ..	3·0 „
„ 20 „	0·60 „ ..	3·20 „

Second dog, weighing 10 kg., pancreas extirpated six days. Injection of 2 mg. adrenalin into the saphena vein; the blood sugar, within the following half hour, remains at 3 g. per litre:—

	Blood sugar.		Blood sugar.
Before adrenalin	.. 3 g.	After 20 min.	.. 3 g.
After 10 min.	.. 3 „	„ 30 „	.. 3 „

Such facts are not stated if the extirpation of the pancreas is not complete, and a dog which had the pancreas removed 13 days before, but had still got a stump of gland, as it was shown by autopsy, showed an adrenalinic hyperglycæmia:—

Dog weighing 9 kg. had its pancreas extirpated, on May 21st, was injected on June 4th with 2 mg. adrenalin:—

	Blood sugar.
Before	1 g.
After 15 min.	1·30 „
„ 30 „	1·50 „

The animal was killed and a stump of pancreas, about the size of a pigeon's egg, was found close to duodenum.

These experiments prove that adrenalin hyperglycæmia is not produced after extirpation of the pancreas. Finally it is as if adrenalin injected into a dog prevented the action of the glycolytic ferment from the pancreas. Its action on glycose seems an indirect one and is suppressed by the previous suppression of that ferment in consequence of the extirpation of the pancreas.

FRENCH SPAS.

THE French have always had the spa habit. No country in the world is richer in mineral springs, and besides such well-known spas as those of Aix-les-Bains, Evian, Contréxéville, or Vichy, there are literally hundreds of other resorts dotted about in the hills and plains of France, to which the great and little bourgeoisie repair each year, as a matter of duty and inclination, to spend a pleasant holiday and cure their bodily ills. The French can justly claim that they have curative waters for almost every disease under the sun; some, such as those of the copper springs of Saint Christau, quite useful in skin affections, are the only ones of their kind as yet discovered.

The Romans were the first to exploit the natural waters of the country; Aix-les-Bains, "queen of resorts and resort of queens," was fashionable even in their days, as it was in the times of Charlemagne and Henri Quatre. Néris-les-Bains, in the Bourbonnais, was the Aquæ Neriæ of the Romans, and the remains of their ancient baths can still be seen at Royat in the Auvergne. The greatest numbers of medicinal springs are to be found in the Pyrenees, the Vosges, and the Auvergne, all places that deserve to be better known to England. The French have been backward in advertising their health resorts; content to benefit themselves, they have left it to the [illegible]ns and Austrians to cry aloud the virtues of the spas in no way superior, and often inferior, to their own.

The Pyrenees, now made accessible, are extraordinarily rich in mineral springs of every variety, particularly those impregnated with soda and sulphur. Luchon, with its highly rádio-active waters, and Cauterets, with its 22 springs containing both argon and helium, are perhaps the most famous, the latter being the classic resort of patients afflicted with chronic catarrh of the nose, throat, and respiratory organs. Salies-de-Béarn is popular amongst those suffering from debility and wasting complaints, and is much frequented by Frenchwomen of all classes, as is Saint Sauveur in the Luz valley. There is Vernet-les-Bains for arthritis, Le Boulou, called "the Vichy of the South," for stomach and liver disorders, Barèges and Eaux-Chaudes for rheumatism, Aylus for gout, and Eaux-Bonnes, called "Eaux d'Arquebusades" in the time of François Premier because of its healing properties in gunshot wounds.

Auvergne, the geological heart of France, has more than 300 springs that are turned to account, the best known being Le Mont-Dore, La Bourboule, Royat, Chatel-Guyon, and Saint-Nectaire. The radio-active waters of La Bourboule, which is pre-eminently a health resort for children, are replete for anæmia and diabetes; those of Chatel-Guyon for diseases of the digestive apparatus and the intestines; Saint-Nectaire, with its "mineral lymph," is popular for albuminuric cures, Mont-Dore for the treatment of asthma, bronchitis, and other nose and throat ailments, whilst Royat is recommended for disorders of the circulation. Vichy, whose bottled waters for stomach, liver, kidney, and other organic complaints are sold in every chemist's shop throughout the world, is also in this neighbourhood, standing on a plateau, with a cluster of smaller and less expensive spas around it. Vittel and Contréxéville, whose springs were first brought to public notice in 1760 by Dr. Bagard (physician to Stanislas, of Lorraine, ex-King of Poland) are well known to English sufferers from liver and kidney diseases, diabetes, and gout, as they are only a day's journey from London. Other spas in the mountainous Vosges district are Plombières, Luxeuil, Bains-les-Bains, Martigny, and Bussang.

Lastly, Biarritz, widely known as a seaside resort, has waters of much curative value for scrofulous and lymphatic subjects, whilst Evian on Lake Geneva is famous for its diuretic springs.

OCCIPITALISATION.

INTEREST in sacralisation of the fifth lumbar vertebra has extended to synostosis occurring at the other end of the vertebral column. The most interesting form of synostosis (or "occipitalisation"[1]) of the atlas is the unilateral variety which results in an inclination of the head towards the affected side, to which is often added a certain amount of rotation, the resulting attitude precisely resembling that in a muscular torticollis, with which, indeed, the anomaly is often associated. Normally flexion and extension of the head remain free; only the lateral movements are impeded. Great difficulty is often experienced in separating the jaws widely so that radiography by the mouth is often impossible. There is frequently but not always an accompanying kypho-scoliosis, and often also some cranio-facial muscular atrophy of the affected side. Occasionally the malformation is not perceived until as late as the twentieth year. Torticollis of bony origin is distinguished from muscular torticollis by the less-marked rotation of the head, the unretracted sterno-cleido-mastoid, the marked limitation of lateral movement and its later appearance, for it is seldom observed before the age of 3 or 4 years. Radiography provides conclusive evidence when it is possible to take a picture through the buccal orifice.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of
Professor CHARLES ACHARD, PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PARIS, AND Dr. CHARLES FLANDIN, D.S.O., CHEF DE CLINIQUE À LA FACULTÉ DE PARIS.

THE PATHOGENESIS OF HÆMORRHAGIC PANCREATITIS.

BY
LÉON BINET, CHEF DU LABORATOIRE DE MÉDECINE EXPÉRIMENTALE À LA FACULTÉ DE MÉDECINE DE PARIS,
AND
PIERRE BROCQ, PROSECTEUR ET CHEF DE CLINIQUE, À LA FACULTÉ DE MÉDECINE DE PARIS.

HÆMORRHAGIC pancreatitis can be recognised by a clinical syndrome, often of a striking character, to which *Dieulafoy* has given the suggestive name "*the pancreatic drama*"; anatomically the condition is characterised by two orders of lesion. These are: (1) a pancreatic hæmatoma, which transforms all or part of the gland, normally small, pink, and soft, into a gross, red, tender mass; (2) ivory-white blotches of fat-necrosis, commonly called "taches de bougies," especially abundant on the pancreas and great epiploön, but sometimes disseminated throughout the abdominal cavity, for they can be detected on the kidney and spleen and even in the pelvis. Moreover, we find habitually in the peritoneum a bloody effusion of variable quantity.

Experimental Demonstration of Hæmorrhagic Pancreatitis.

This group of associated lesions can be reproduced experimentally on the dog. Care must be taken to anæsthetise the animal either with chloralose or with *a mixture of morphine and chloroform.* Atropine-morphine mixture must not be employed because of the arresting action exercised by atropine on the pancreatic secretion. On the other hand, as one of us has *shown in collaboration with L. Morel*[1] the animal ought to be in full tide of digestion. For this reason, about three hours before the beginning of any experiment of the sort, the animal should be given a *meal rich in meat and fat.* All precautions, of course, must be taken against the errors that would arise from any infection during the operation.

Simple ligature of the chief pancreatic duct is not followed by *hæmorrhagic pancreatitis*, that is to say that arrest of the pancreatic secretion, such as can normally occur in the ducts, cannot by itself give rise to the syndrome which we are considering. On *the other hand, the pancreatic duct having been* ligatured near the duodenum, the injection into it of various fluids will give rise to typical hæmorrhagic pancreatitis, subacute or acute, generalised or discreet, *appearing in from 24 to 48 hours*, and apparent on examination of the animal after it has been killed.

We do not intend here to pass in review all the substances capable of giving rise by injection into the pancreatic duct to hæmorrhagic pancreatitis. The occurrence of the lesions described above has been ascertained to succeed the employment of irritant solutions—formol, chloride of zinc, hydrochloric and *nitric acid (V. Oxner), fatty acids (Jean Camus and Ph. Pagniez)*, chromic acid, and other agents. We are only taking into consideration here *the body whose action can be incriminated in the* pathogenesis of hæmorrhagic pancreatitis produced clinically.

1. *The Rôle of the Bile in the Experimental Reproduction of Hæmorrhagic Pancreatitis.*

In 1856 Claude Bernard, injecting into the pancreatic duct of a dog a mixture of bile and sweet oil, observed that the animal died in eighteen hours from pancreatic hæmorrhage. Opie, in 1901, injected pure bile and made the same observation. In 1906 Flexner observed that in these experiments the salts were the active principles of the bile. The experiments were often attended with no results, but one of us in *collaboration with L. Morel*[2] in 1913-1914 *has demonstrated* that to obtain hæmorhagic pancreatitis in constant fashion by the injection of bile into the duct, it was necessary that this gland should itself be in the state of secreting—*that is to say, that the animal ought to be digesting at the moment of the experiment.* The meal before the operation can be replaced by an injection of secretin which has the same result. Fourteen dogs during the process of digestion had injected into the pancreatic duct 5 c.c. of their own bile, derived aseptically by puncture of the gall-bladder. The injection was followed by ligature of the duct. From these 14 experiments positive results were obtained in 12; acute cases (6); the animals dying between 20 and 48 hours, and subacute cases (6), the animals surviving. The necessary condition for *obtaining constant results was found to be that the* pancreas should be actively secreting, as indicated by the fact that the injection of secretin has the same effect as a pre-operation meal.

It can be urged against these experiments that the pancreatitis followed traumatism, whether by the injection of the bile in the canal of Wirsung, or by the retention of the pancreatic juice above the ligature. In reply to these objections one of us[3] has carried on with Morel a series of researches with the object of testing the pathological composition of bile and pancreatic juice outside the pancreatic excretory system. *To bring about the new conditions* we left open in the abdomen the cut pancreatic duct and gall-bladder. The animals died within 22 to 36 hours, with free hæmorrhagic exudation in the peritoneum, and many large patches of fat-necrosis.

2. *The Rôle of the Intestinal Secretion in the Experimental Reproduction of Hæmorrhagic Pancreatitis.*

The injection of the secretions of the duodenum into the pancreatic duct, followed by ligature of the duct, brings about intense hæmorrhagic peritonitis. This *fact, demonstrated in 1906 by Polza*, and verified by us, is very complex in origin. In the duodenal secretion different constitutents contribute to give rise to hæmorrhagic peritonitis—for example, the bile, the *hydrochloric acid* of the gastric juice, if this has not been neutralised, and finally entero-kinase.

This last alone, among the factors of the intestinal secretion, can operate in *the genesis of pancreatitis as* the result *of* its own action on the trypsinogene, which it transforms into active trypsin; we have been able to demonstrate this reaction by working with pure intestinal secretion, alkaline, *and free from* bile.[3]

The intestinal secretion which we employed was human, collected from a case of intestinal fistula, which was an exact pathological reproduction of the experimental fistula of Thiry. It opened into a loop of the damaged gut, 40 cm. in length, and was closed at each end so as to be shut off from the rest of the intestine. The collected secretion was pure, without food material or bile. *It was clear, viscid, and alkaline,* while the presence of entero-kinase was demonstrated by the method of H. Bierry and V. Henri. Into three test-tubes we poured 5 c.c. of milk deprived to a great extent *of its fat.* To the first tube we added 20 drops of pancreatic juice obtained after the injection of secretin from a temporary fistula in a dog. To the second tube we added the same quantity of pancreatic juice and five drops of intestinal secretion collected from our case of intestinal fistula. To the third tube we added five drops of intestinal secretion without pancreatic juice. These three tubes were placed in a bain-Marie warmed to 37° C. for 20 minutes, when only the second tube became transparent, owing to the digestion of the casein, thus demonstrating in the time of its inception, was bound to attract a great deal of attention elsewhere. And now in the metropolis the London Hospital, St. Thomas's Hospital, and the Royal Free Hospital have embarked upon a similar adventure.

◆

Acute Hæmorrhagic Pancreatitis.

DISEASED conditions of the pancreas are notoriously difficult to diagnose and, moreover, unsatisfactory to treat in many instances. It is natural to expect, or at any rate to hope, that increase in our knowledge of their pathology, and improvement in our means of diagnosis, may lead to the development of satisfactory methods of treatment. The deep situation of this gland and its important anatomical relationships combine with its complex functions to render its examination and investigation difficult. The problems are further complicated by the facts that the internal secretory functions of the pancreas are profoundly influenced by the activities of other endocrine glands, notably the suprarenals, thyroid and pituitary, and that the effects of want of balance between these various inter-related endocrine functions, though recognised and generally admitted, are imperfectly understood and not yet delimited. The problem of the diagnosis of pancreatic disease is of especial importance in the more acute lesions of that organ, more particularly in that variety known as acute hæmorrhagic pancreatitis, in which the only hopeful form of treatment at present, and in the majority of cases, is early operation.

We publish in the French Supplement to THE LANCET this week a paper by MM. LÉON BINET and PIERRE BROCQ, which is an important contribution to the pathology of this condition. They point out that the morbid anatomy, as revealed by operation or necropsy, is characteristic, comprising a hæmorrhagic change in the pancreas itself, whereby it becomes converted into an enlarged, red, "hæmatoma," while we find ivory white areas of fat-necrosis in the pancreas itself, in the omentum, and sometimes widely distributed in the abdomen and pelvis. With these characteristic and almost constant appearances there is frequently a blood-stained effusion into the peritoneum, often of considerable quantity. This distinctive morbid anatomy is familiar to pathologists and surgeons, who are often confronted with it unexpectedly. The question therefore arises as to whether the clinical manifestations afford sufficiently definite indications to allow a diagnosis to be made. Sir ARCHIBALD GARROD, in his interesting Schorstein lecture on the Diagnosis of Disease of the Pancreas[1] pointed out that there are three main groups of diagnostic indications. The first of these comprises the actual symptoms and clinical signs. One of these is pain, often sudden in onset, severe in character, and referred to the back as well as to the abdomen. Other symptoms are persistent vomiting, constipation, a moderate degree of cyanosis, rapid pulse, tenderness, and sometimes swelling or tumours in the upper abdomen. The aspect of the patient is that of severe abdominal disease, and the constitutional symptoms are often profound. Unfortunately, the concurrence of all these symptoms cannot be regarded as characteristic—indeed, they are equally suggestive of some acute abdominal catastrophe, such as intestinal obstruction, for which this condition is not infrequently mistaken. Even when sufficient enlargement of the pancreas occurs to produce a palpable and tender tumour, or to cause pressure on adjacent structures, it usually presents no characteristic features, though resonance in front of it, due to the anterior relationship of the stomach, may give a suggestive indication. The second group of symptoms comprises those due to defects in the digestive or external secretion of the pancreas, as demonstrated by examination of the fæces, the proteins, fats, and carbohydrates of the diet being all concerned. The third group includes manifestations of interference with the internal secretory or endocrine functions of the organ, particularly its relationship to sugar tolerance and glycosuria. Both the external and internal secretory functions of the pancreas are matters permitting of laboratory investigation, and in view of the dubious indications at the bedside, it is natural to turn to the laboratory for aid. The tests of pancreatic efficiency are very numerous. In regard to the external secretion alone, GARROD has referred to no less than 12. There are in addition those of the investigation of the presence of glycosuria and the degree of sugar tolerance. There is also the well-known adrenalin mydriasis reaction of LOEWI. These tests were described and critically studied in an important article by Dr. MACKENZIE WALLIS in the *Quarterly Journal of Medicine* for October, 1920. Unfortunately, as both GARROD and WALLIS insist, none of these tests individually affords consistent indications. On the other hand, when several of them give positive indications they are of great value. This is well shown in the protocols of a considerable number of cases recorded in WALLIS's paper, and we may quote his general conclusions to the effect that the coexistence of an increased diastase content in the urine, LOEWI's adrenalin mydriasis, and the presence of glycosuria afford strong evidence of faulty function of the pancreas, while the occurrence in addition of creatorrhœa and steatorrhœa render it certain. In view of the acute character of some pancreatic lesions, the fact that the tests just mentioned take less time for their performance than some of the others renders them of special value—for example, GARROD states that the urinary diastase and adrenalin mydriasis tests can both be carried out within an hour.

Other questions of great interest in connexion with this disease are those concerned in its pathology, prognosis, and treatment. At present we have little or no basis on which to construct a satisfactory prognosis. We may refer our readers to an interesting paper on two cases of this disease by Mr. ALWYNE T. COMPTON and Mr. FRANK HEBER, who point out the gravity and the uncertainty of prognosis (p. 130). In one of their cases a successful result occurred after operation in what appeared to be an unpromising case. Another case, progressing to cyst formation and cured as the result of two operations, is recorded by Dr. R. B. CARSLAW on p. 132. The only form of treatment which seems to give any hope of success at the present time is surgical—namely, opening the abdomen and dealing with the pancreatic condition found whenever this is practicable. In view of the difficulties in diagnosis, prognosis, and treatment, any researches tending to throw light upon the pathogenesis of this disease and to elucidate the mode of production of its characteristic morbid anatomy must be welcome. MM. BINET and BROCQ's observations in the paper to which we have already referred are of great interest in this connexion. They conclude that the condition of the pancreas and of the fat in its neighbourhood are the result of auto-digestion, due to the activation of the pro-ferments

---

RESEARCHES ON ADRENALIN DIABETES.

BY CH. ACHARD
AND
A. RIBOT AND LÉON BINET.
CHEFS DE LABORATOIRE AT THE FACULTÉ DE MÉDECINE OF PARIS.

SINCE Blum and then Zuelzer described, in 1901, the glycosuria following the subcutaneous or intravenous injection of suprarenal extract a great deal of work has been done on the effect of suprarenal extract and adrenalin on carbohydrate metabolism.

Achard and Desbouis[1] in 1913 have shown that the injection of suprarenal extract produces a general glycolytic insufficiency, that is a decrease of the power of the tissues of burning glycose. After an injection of adrenalin the injection or ingestion of glycose is not followed with an increase of the carbon dioxide discharge through the lungs.

We have extended those experiments on adrenalin diabetes, and we are submitting now three series of researches:—

1. On the influence of adrenalin on the glycolytic power of organism, indicated by means of provoked hyperglycæmia.
2. On the relations between adrenalin and pancreatic extract and concerning their effects on glycolytic power.
3. On the effect of adrenalin on the depancreatised animal.[2]

1. *Effect of Adrenalin on the Glycolytic Power of Organism.*

For that purpose we have studied in the dog the characters of the hyperglycæmia provoked by an injection of glycose, and, those characters being known, the variations of this hyperglycæmia when a certain quantity of adrenalin is injected together with sugar. In every experiment glycose was injected in water-solution (35 g. per litre), and blood takings were done at first before the injection and then every ten minutes following the injection. Our dosings have been made according to Epstein's method, which allows numerous takings of blood without decreasing the volume of blood in a great proportion, and therefore without altering the total quantity of blood sugar. The duration of the hyperglycæmia provoked by the injection of glycose seemed to us a most important point, susceptible of showing the aptitude of organism for fixing this sugar. In a well constitutioned dog we obtained the following results:—

First dog, weighing 12 kg., was injected with 12 g. of glycose; after two minutes the quantity of blood sugar had gone from 1 g. per litre up to 3·10 g.; the glycæmia had come down to the starting-point after 40 minutes.

Second dog, weighing 19 kg. was injected with 12 g. of glycose; after two minutes the blood sugar had gone from 0·90 g. up to 2·65 g., and gone down to 0·90 g. after 30 minutes.

Third dog, weighing 19 kg., was injected with 10 g. of glycose; the blood sugar had gone from 1·05 g. up to 2·85 g. after two minutes, and came back to the starting-point after 20 minutes.

Fourth dog, weighing 15 kg., was injected with 3·50 g. of glycose; the blood sugar had gone after two minutes from 0·95 g. up to 1·40 g., and was normal after 20 minutes.

Fifth dog, weighing 33 kg. was injected with 7 g. of glycose; after two minutes the blood sugar had increased from 1·15 g. to 1·95 g., and back to 1·15 g. after 10 minutes.

From those experiments, chosen among several others, we can conclude that the quantity and duration of hyperglycæmia provoked by the injection of glycose are evidently in proportion with the quantity of the glycose injected. The duration of that phenomenon gives very clear indications, and we can admit that with 0·50 g. of glycose per kg. the hyperglycæmia lasts about 20 minutes, and with 1 g. per kg. it lasts about 40 minutes. We might wonder what becomes of the injected glycose; one part is eliminated through the kidneys, as it is shown by a glycosuria following the hyperglycæmia; the rest is either fixed in or burnt. In fact, the analysis of gases in venous blood or in expired air shows the quick combustion of the assimilable sugar.

The comparative study of the quantity of sugar after the injection of assimilable glycose and, on the other hand, after the injection of unassimilable lactose clearly proves the part of the destruction and fixation of the sugar during the phenomenon.

A dog weighing 22 kg. was injected with 15 g. of glycose; hyperglycæmia disappeared 45 minutes after. Some days later it was injected with 15 g. of lactose; the quantity of sugar was double 45 minutes after; 0·78 g. at the beginning, 1·95 g. after 45 minutes.

What becomes of hyperglycæmia when adrenalin is injected together with glycose? We have studied that, considering in each experiment the effect of glycose alone, then the effect of adrenalin, and lastly the effect of both together.

A dog weighing 15 kg. was injected at first with 3·50 g. of glycose, two days later with 1 mg. adrenalin, and lastly, two days later with 3·50 g. of glycose + 1 mg. adrenalin:—

TABLE I.

—	Rate of blood sugar after an injection of		
	3·50 g. glycose.	1 mg. adrenalin.	3·50 g. glycose + 1 mg. adrenalin.
Before	0·95 g.	0·95 g.	0·95 g.
After—			
2 min. ..	1·40 ,,	—	1·70 ,,
10 min. ..	1·10 ,,	1·40 ,,	2·10 ,,
20 min. ..	1·0 ,,	1·20 ,,	1·70 ,,
40 min. ..	—	0·92 ,,	1·30 ,,
1h. 20 min.	—	—	1·10 ,,
2 hrs. ..	—	—	0·95 ,,

From this experiment (Table I.) it results that the addition of adrenalin to glycose brings an increase of sugar greater than the sum of the both increases brought by adrenalin alone and glycose alone. Besides this hyperglycæmia lasts longer, since it lasted after 1 h. 20 m. It is as if the organism, under the influence of adrenalin, could no longer fix in and burn sugar; its glycolytic power seems absent. Those experiments seem to be capable of practical applications; in therapeutics it seems that there is incompatibility between glycose and adrenalin; the serum composed of both glycose and adrenalin seems not to be used.

2. *Relations between Adrenalin and Pancreatic Extract with regard to their Effect on the Glycolytic Power of Organism.*

The hyperglycæmia, provoked by the injection of glycose in the veins, is exaggerated as rate and duration, when in the same time adrenalin is injected. On the contrary, it was experienced that the hyperglycæmia decreased when fresh pancreatic extract was injected—that is, that adrenalin produces a glycolytic insufficiency, and pancreas, on the contrary, increases glycolyse. Moreover, the pancreatic extract, added to adrenalin, inhibits the effect of adrenalin, as shown in the following experiment (Table II.):—

TABLE II.

Time of examination.	Rate of blood sugar after injection of—		
	7 g. glycose.	7 g. glycose + 1 mg. adrenalin.	7 g. glycose + 1 mg. adrenalin + aqueous pancreatic extract.
Before	1·15 g.	0·95 g.	0·95 g.
After 2 min. ..	1·95 ,,	1·80 ,,	1·25 ,,
,, 10 ,, ..	1·15 ,,	1·45 ,,	0·95 ,,
,, 20 ,, ..	—	0·95 ,,	—

3. *Mechanism of Adrenalin Hyperglycæmia.*

We have tried to solve that problem by studying the effect of an injection of adrenalin after the extirpation of pancreas. It is a problem so much the more interesting as the connexions between the suprarenal nearer to that of butter, is comparatively rich in this vitamin. These two margarines possess the same gross energy value, yet their true food value is very different. In spite of such considerations, not only the War Office but other Government departments are prepared to accept a classification of foodstuffs based on thermal values. It is an undesirable perpetuation of the doctrine promulgated in the well-known report issued in 1916 by a Committee of the Royal Society on the Food Supply of the United Kingdom. This report was prepared at a time of national stress, when a stocktaking of our food-supply and its evaluation on some sort of basis was a necessity. The inquiry served its purpose, and we do not for a moment think that the distinguished members of that Committee would claim more for it. It must also be borne in mind that the presence of vitamins, even coupled with thermal values, by no means represents finality in food values; the appearance, the flavour, and the many combinations of foods which are the outcome of our civilised experience all play their part in the physiology of nutrition.

TROPICAL SANITATION.

THE rapid development of tropical medicine has necessitated the devotion of a considerable amount of space in the *Tropical Diseases Bulletin* to the consideration of sanitation and hygiene in the tropics. From 1914 up to the present this demand was met by the issue from time to time, as occasion warranted, of special numbers of the *Bulletin* entitled "Applied Hygiene in the Tropics," edited by Colonel W. G. King, I.M.S. (ret.). These numbers were much appreciated by sanitarians throughout the tropics, containing as they did a large amount of useful information especially welcome to those sanitary officers whose duty lay in tropical countries during the war. The development of sanitary science in the tropics since the commencement of the war and the establishment of a special department of sanitation and hygiene in the schools of tropical medicine in this country have rendered desirable the regular publication of a summary of recent progress in that science. A new departure has therefore been made by the quarterly issue of supplements to the *Bulletin* entitled "Sanitation Supplements."[1] The first of these is under the editorship of Colonel W. W. Clemesha, I.M.S. (ret.), an authority on Indian sanitation, who is at present lecturing on that subject at the London School of Tropical Medicine. The supplement contains 82 pages, abundantly illustrated with plans, diagrams of appliances, and photographs of various sanitary undertakings. A résumé is given of recent work in the control of malaria, with special reference to the campaign in Dar-es-Salaam. Consideration is also given to yellow fever, kala-azar, yaws, tuberculosis, enteric, influenza, leprosy, typhus prevention in China, and plague. There are also sections dealing with conservancy appliances, milk in the tropics, small-pox vaccination, disinfection, vital statistics, and miscellaneous questions; reviews of books are included. The second number is concerned to a great extent with recent work on malaria prevention, with especial reference to town planning in the tropics. The picture on p. 96 of the model town of La Boca at the Pacific entrance to the Panama Canal is unusually interesting. The section devoted to the prevention of disease includes an account of the intensive treatment of yaws in Grenada, from which we learn that in 1919 3000 cases were injected with novarsenobillon, and of these 808 were cured, at an expenditure of £1739 9s. 6d. The conservancy section deals with the latest investigations upon sewage disposal; ample space is again devoted to water, milk, vaccination, and disinfection. Vital statistics receive due attention, and Colonel Clemesha deserves commendation for the attractive manner in which he presents a subject in which the majority of medical men take insufficient interest. From this short account it may be inferred that the Sanitation Supplements will well maintain the reputation of the *Tropical Diseases Bulletin*. Though primarily intended for medical men, future numbers will contain sanitary hints which can be appreciated by any person interested in sanitary progress throughout the world. These will be welcomed by officials in India and elsewhere, in so far as they may be spared the labour and tedium of wading through blue-books.

VICTOR VON URBANTSCHITSCH.

IT is barely a year since we recorded the death of Adam Politzer, and now we regret to note the death of Prof. von Urbantschitsch, who succeeded him as Director of the Aural Clinic in the University of Vienna. Urbantschitsch passed his life in Vienna, where he was born in 1847, in the study of otology and became, on Politzer's retirement in 1907, director of the Aural Clinic, from which he in turn retired three years ago at the age of 70. Though not so great a man nor so famous an otologist as his predecessor, he was an original worker of much ability, and did good service in improving the education of deaf-mutes and in the study of tuning-fork tests of deafness. His text-book of otology is a standard work which has run into five editions.

THE FUNCTIONS OF THE OTOLITHS.

THE complicated functional relations of the labyrinth of the ear to the muscular apparatus of the body are far from being fully revealed to us. The investigations of A. de Kleijn and R. Magnus of Utrecht[1] add considerably to our knowledge. It must be kept in mind that there are the semicircular canals on the one hand and the utricle and saccule, with their otoliths, on the other. Besides the effects on movement the labyrinth discharges tonic reflexes, dependent on the position of the head in space, such as (1) tonic labyrinth reflexes on the musculature of the body; (2) a labyrinth posture reflex; and (3) tonic labyrinth reflexes on the muscles of the eyeball. These reflexes are mediated by the otoliths, while the labyrinth reflexes on movements (turning and progressive movement) are discharged from the semicircular canals. The authors adduce evidence of the connexion between the otoliths and the tonic labyrinth reflexes, which disappear as soon as the otoliths are dislocated and, as it were, cast aside, by submitting the animal to the action of a centrifuge making 960–1000 revolutions per minute for a period of 1½–2 minutes, a method originally devised by Wittmaack. The reflexes of movement, however, remain after the removal of the otoliths. The authors deal first with the relation between the position of the otoliths in space and the maximum and minimum of the tonic reflexes. The tonic labyrinth reflexes of the extremities depend on the otoliths of the utricle, since after removal of the labyrinth canals the tonic limb reflexes remain. If the sacculus otolith was the agent the reflex would be altered on removal of the labyrinth. Each utricle seems to be in functional relation with the extensor muscles of both sides of the body. The tonic labyrinth neck muscle reflexes seem also to be in relation with the utricle reflexes, but in this case the neck muscles of one side of the body are in functional connexion with the opposite utricle otolith. The labyrinth posture reflexes are in connexion with the saccule and have their centre in the mid-brain, while the saccule otoliths are in relation to the tonic labyrinth reflexes of the eye movements. In the cases in which, after centrifuging guinea-pigs, all the labyrinth reflexes were present or returned after a time, no histological changes of any consequence were observed in the otolith apparatus. In all the uncomplicated cases in which the tonic labyrinth reflexes of the extremities, the posture, and the compensatory positions of the eyes

THE LANCET.

LONDON: SATURDAY, JULY 16, 1921.

The Position of the Voluntary Hospitals.

Hospital authorities have had much to think about during the last week. Lord Cave's Report,[1] it will be remembered, put out certain schemes under which contributions could be obtained in mass from the public without, in the opinion of the Committee, interfering with the voluntary principle of conduct. And, as a main premiss, the Committee regarded the coöperation of the National Health Insurance Commission as essential to the maintenance of that principle. The social circumstances of the country, to meet which voluntary hospitals throughout the whole of their nineteenth century developments were designed, were changing rapidly before the war, and the fluctuations of prosperity, though making a severe charge upon hospitals, were really representative alike of the national position and of enlarged scientific views. The hospitals were coming to be regarded no longer as being run by the medical profession as homes of refuge in the last resort for the sick and suffering poor. A general spirit of intelligence had revealed to the public, as well as to the medical profession, that these institutions should be used in as early a stage as possible, so that curable cases should be treated and intractable complications obviated. The tangible outcome of the spread of public intelligence was hospital abuse—often of the most flagrant sort. While the charities were thus being exploited, the expense of maintaining the patients and administering the hospitals went up, while the cost of medical education—a thing apart from the financial side of hospitals though otherwise affiliated in every direction with hospital work—was quadrupled. Thus, some ten years ago, everyone connected with the administration of voluntary hospitals—the administrator, the doctor, the patient, the teacher, and the taught—was struggling in a morass. Then came the war, when, in circumstances which have been set out over and over again in every newspaper in the kingdom, and in every hospital report that has appeared, it became clear that the voluntary system of support must either be reinforced or make way for methods of financial stability.

At this parting of the ways the road which we consider the right one—namely, the maintenance of the voluntary system—was advocated on all sides, and advocated with a unanimity that was not a little remarkable considering the reiterated assurances from pessimists that the system was already dead. Red Cross and the great Hospital Funds declared their belief that the voluntary system had not only a splendid past but a splendid future if the public could be induced to coöperate with some measure of adequacy; and Lord Cave's Committee crystallised this view by putting out schemes in furtherance of this happy consummation. Last week a Conference of hospital authorities was held at the Mansion House, Lord Stuart of Wortley, Chairman of the King's Fund Policy Committee presiding, the object being to discuss the alternatives set out by Lord Cave's Committee. That Committee, it may be remembered, drew attention to a number of steps which might be taken to improve the financial position of voluntary hospitals by managers and by the public. They considered, for example, that managers might review expenditure, particularly in the light of comparative costs which could be ascertained by the general adoption of a uniform system of accounts; might establish a coöperative buying of drugs, apparatus, stores, and some kinds of provisions; might remove convalescent cases to auxiliary hospitals; coördinate appeals for subscriptions; further develop new sources of income, such as subscriptions from wage-earners and employers, and other contributory schemes; and might obtain larger contributions from Approved Societies. The last of these suggestions was made the subject of an interim report by Lord Cave's Committee, and it is a concrete indication which is bound to come under early notice. But with regard to the various contributory schemes which have been put forward on business or philanthropic grounds, time may elapse before they come to trial.

One scheme, however, is in actual being. The Sussex Provident scheme was set out in The Lancet, at the time of its publication some months ago, in the words employed by its originator Dr. Gordon Dill, senior physician to the Royal Sussex County Hospital.[2] Under this scheme residents in Sussex, who pay the annual subscription—£1 per annum for a single member, £1 10s. for a married couple without children or a widow or widower with one child, and £2 for married people with children—obtain a number of valuable benefits hitherto out of their reach. The scheme does not aim at providing ordinary medical attendance or at giving benefits supplied by the State or local authorities, but the medical attendants of members are able to arrange for private consultations at the following hospitals: Royal Sussex County Hospital, Royal Alexandra Hospital for Sick Children, Brighton and Hove Hospital for Women (for Obstetrics and Gynæcology), Brighton and Hove Provident Dental Hospital (for Dental Surgery), Brighton, Hove and Preston Dispensary, Sussex Eye Hospital (for Ophthalmic Cases), Sussex Throat and Ear Hospital (for Diseases of the Throat, Nose, and Ear), Lady Chichester Hospital (for borderland Mental Cases), and New Sussex Hospital for Women and Children. Any treatment found to be necessary as the result of this consultation is given at the hospital, while patients confined to bed are visited by consultants at their homes. At the Dental Hospital members receive ordinary dental treatment, and dentures are supplied at hospital rates. All the resources of the Stephen Ralli Memorial Laboratory at the Royal Sussex County Hospital are available, including bacteriological and pathological investigations, vaccines, and X ray examinations and treatment; also massage and electrical treatment. All who are insured under the National Health Insurance Acts come within the scope of the scheme, and for others the maximum income limit is £260 for single members, £400 for married people without children, or a widow or widower with one child, and £500 for a family. All subscriptions received during the year will be divided among the coöperating bodies in proportions which have been already agreed upon for the first year. The scheme, which has been working successfully for several months, immediately gained the approval of all branches of the medical profession in the county of its origin, and, as we said first to discover the real germinal vesicle in the human and mammalian ovum, and to demonstrate the nature and significance of that body." Working on the subject of the blood, in 1852 he contributed to *Trans. Roy. Med.-Chir. Soc.* his paper describing the phenomena of inflammation as it occurs in the bat's wing, his previous observations having been confined to the web of the frog's foot. He also described the amœboid movements of the white blood corpuscles. These are his discoveries which rank as of supreme importance, but to appreciate the whole range of Wharton Jones's achievement the reader should consult his bibliography, containing 68 elaborate titles of books and papers, which concludes Sir Rickman Godlee's biography. His fine work in ophthalmology has been well described by his biographer in THE LANCET.[2]

---

[2] The Lancet, 1921 i., 153.

Wharton Jones's personality was interesting and prickly. He is described by Huxley, his pupil at Charing Cross, as lecturing to a remote generation of students, fathers of the great scientific movements of later years. "The true *lumen siccum* of science glowed in every proposition which fell from the lips of the pale adust little man as he stood with downcast eyes, and fingering his watch chain, at one corner of the table. He never had any notes, but the lectures would have read perfectly well if printed straight off. I used to wonder at and envy his 'facility.'" He lived a recluse life, was ultra-susceptible, given to tears, "fundamentally a tender-hearted, sentimental Celt (a Cymric Celt)," says Dr. Robertson, of Ventnor, who knew him well in his closing years. Shyness, pride, and a kind of perverted love of truth which led him to argue most logically at times from passionately-held false premisses, made him probably the unhappiest of men. He loved polemics, imagined slights, and showed a touch of genius in the manner in which he could create a quarrel. His published series of letters to James Whatman, F.R.S., M.P. for Maidstone, is a model instance of what Whistler called "the gentle art of making enemies." He believed that heirlooms and much wealth, which should have come to the Joneses, had been retained by the prosperous Whatmans. The squabble centred in Wharton Jones's great-grandmother, an Elliston by descent from Alestan, a freeman of Essex, whose land had been confiscated in 1066. Wharton Jones was intensely proud of his pedigree by the distaff side, and this pride influenced his passionate character and led to his impoverishment. He gave time to antiquarian, historical, and heraldic researches, which had better have been spent in the service of his professorship. Had he been a man of means he might have happily justified his opinion that "historical and ordinary anatomico-physiological researches have much in common." As it was he lost practice, made enemies, ceased to be in touch with the world, and at last hunger knocked at his door. In 1881 he was found by Sir John Tweedy, his successor at University College, starving by a fireless grate on a freezing day. The pupil saved the master's life, got him food, collected money for him, eventually obtaining for him two pensions. It is a charming story. The old professor ended his days at Ventnor, never suspecting who were his real benefactors. He left a substantial sum of savings to a well-known man, who had been quite ignorant of the affair of 1881.

HYDROCYANIC ACID AND SANITATION.

THE May issue of the *Office International d'Hygiène Publique* contains details of recent legislation in the United States, Italy, and Sweden, concerning the use of hydrocyanic acid for fumigation of ships and buildings, together with communications on the subject made by Drs. Lutrario and Wawrinsky, Italian and Swedish delegates to the April–May session of the *Office International*. In all cases the regulations emphasise the dangers attendant upon the employment of this means of deratisation and disinfestation; elaborate precautions are demanded from the responsible port and sanitary authorities, and, these being observed, the results of the processes appear most satisfactory. The properties of hydrocyanic acid, as prepared for sanitary use, vary. In Italy the proportions used are sodium cyanide 1 g., sulphuric acid 0·8 c.cm., water 3 c.cm.; in Sweden, sodium cyanide 1 g., sulphuric acid 1·5 c.cm., water 4 c.cm. The acid is very destructive of rats and other warm-blooded animals; cockroaches, flies, mosquitoes, with fleas, bugs, and other parasites, are all exterminated in a period varying with the concentration of gas used. At Rome an exhaustive inquiry was made into generation, diffusion, and chemical action, with special reference to the rat problem; amongst the comprehensive information given as a result of this inquiry it is noted that although woollen stuffs retain a considerable quantity of acid the latter is easily removed by sufficient ventilation or by a raising of temperature. Substances rich in glucose (marmalade, syrup, honey) retain a small amount of acid on their surfaces only. Semi-solids and liquids, it must be remembered, may always retain some of the acid in solution. Cereals, and seeds in general, do not lose their power of germination when fumigated in this way. Merchandise in bulk (e.g., grain), compressed, or in the form of powder (e.g., meal) must be treated in chambers hermetically sealed. The Italian sanitary authorities have fumigated 256 ships during the year March, 1920, to March, 1921; in all, more than 2,300,000 cubic metres of warehouses, dock space, hotels used by emigrants, &c., have been similarly treated; whilst the rapid destruction of mosquitoes in houses and stables by this means has shown hydrocyanic acid to be a valuable factor in the campaign against malaria.

PYELOGRAPHY.

IT was in 1896 that the research of Chapius and Chauvel on the corpse, and of MacIntyre on the living subject, laid the foundations of pyeloscopy. Improvements in X ray technique rendered this method of investigation more and more useful to urologists, until in 1905, Voelcker and Lichtenberg made possible a great advance in the X ray examination of the kidney by injecting the ureter and pelvis with an opaque solution, so revealing changes of form and direction which previously could only be discovered by an operation. The art of pyelography has made great progress in the last 16 years, and developed from a risky procedure into one that is at present rarely fraught with unhappy consequences and is often of the greatest value in diagnosis. The modern technique is described by Drs. C. Beyer and J. De Nobele[1] as follows: "the patient is purged; without any preliminary injection of morphine, the catheter, for preference a No. 12 olivary with two eyes, is passed into the ureter; the cystoscope is removed, the catheter fixed to the thigh, and the patient lying on his back is wheeled into the X ray room . . . . the limbs are flexed on the pelvis to straighten the lumbar saddle . . . . a first radiogram is taken to expose any calculus whose outline might be obscured by the subsequent injection." This is made by a record syringe, the piston of which is pushed home till pain announces that the solution has reached the renal pelvis. A photograph is then taken and examined by the negatoscope, while a finger on the syringe maintains the solution in place. If the photograph is successful, the solution, which is usually 10 per cent. collargol, is allowed to run back and the catheter is withdrawn. In order to avoid accidents the injection must be made very gently and stopped directly the patient complains of pain. the ureteral catheter should be sufficiently fine to allow a reflux of the collargol solution. Several accidents, some fatal, have been attributed to the collargol itself, and the writers above-mentioned suggest that in the future some other opaque solution

John Tweedy, THE LANCET, 1891, vol. ii., p. 1256.

[1] Le Scalpel, May 28th, 1921, p. 530. (This number is devoted entirely to the subject of pyelography.)

recognised that these pro-ferments are normally activated in the intestine by entero-kinase, and it is suggested that under conditions of disease a similar activation *in situ* in the pancreas can be induced by a cyto-kinase derived from the pancreatic cells, by a leuko-kinase produced in the blood, by bacteriokinases generated by bacterial activity, and possibly by the bile and duodenal contents if they regurgitate into the duct. This conception was originally brought forward by PAUL CARNOT and has been developed and submitted to experimental test by MM. BINET and BROCQ. They have investigated the rôle of the bile, of the intestinal and pancreatic secretions, of leucocytes, microbes, and toxins, and of calcium salts on the genesis of acute hæmorrhagic pancreatitis experimentally. They suggest that in some cases an escape or regurgitation of duodenal contents may occur into the pancreatic duct and thus reach the parenchyma of this organ. On this hypothesis the hæmorrhagic and destructive changes in the pancreas are due to activation of the trypsinogen or pro-trypsin—the trypsin thus formed damaging the vessels and the cells. The fat necrosis is also regarded as due to a similar activation of the precursor of the fat-splitting ferment or lipase. These researches emphasise the need for early diagnosis, since they hold out a hope that if the condition leading to the pancreatitis can be recognised sufficiently early it may be dealt with effectively. If the work is confirmed, it may explain the uncertainty of prognosis which presumably depends upon the extent of the pancreatic auto-digestion produced. The whole subject is one which would seem to be ripe for carefully coördinated team-work by physiologists, pathologists, physicians, and surgeons. The difficulties of the problems concerned invest them with a special interest and importance, and sufficient evidence is now available to indicate that they are not insoluble.

◆

Curves of Resistance.

THE processes by which bacteria are killed by hot water or disinfectants have been analysed by several observers. The work of MADSEN and CHICK in this connexion will be familiar, and the question was dealt with at some length by HEWLETT in his Milroy Lectures.[1] The general result of these experiments on the rate of killing has been that bacteria in hot water or phenol die logarithmically—which is to say that the number which die during each time interval is a fixed proportion of those alive at the beginning of it, so that the great majority die at the beginning of the experiment. Thus if the numbers of survivors are plotted against time a curve is obtained of the type of a reversed J, while if the logarithms of the numbers are used the curve is a straight line. The charm of this result is that molecules of cane sugar and some other simple substances break up on the same plan when they are boiled with hydrochloric acid. The difficulty about it is that it is apparently in flat contradiction to the biological law that all measurable qualities of live things vary according to the normal curve or something like it. On this arrangement there should be a few bacteria of exceptionally small resistance, a few of exceptionally high resistance, with the majority graded between these extremes in such a way that most of them are at or near the average value for the whole lot. If such a population is killed off, a few will die quickly and easily, the majority will die moderately fast, and a few will take a long time to kill; plotting the survivors against time will give a curve like a reversed S. An important paper by Dr. J. HENDERSON SMITH,[2] formerly of the Lister Institute and now attached to the department of plant pathology at Rothamstead, on the killing of the spores of the mould *Botrytis* by phenol, may be welcomed as a successful attempt to bring the two views into harmony. He shows that with 0·4 per cent. phenol the curve is sigmoid, and that as the strength of disinfectant is raised it becomes less and less sigmoid, so that with 0·7 per cent. it is of the logarithmic type. Both types of curve are explicable on the assumption that the individual spores differ in resistance and that the resistances are distributed among the individuals approximately in accordance with the normal curve. It is highly satisfactory to find in this way that these lowly organisms conform to the laws which summarise the properties of other live things. The work may also go further and indicate how the properties of dead matter can be brought into line; it is impossible to say at present how large a generalisation is opened up.

Annotations.

"Ne quid nimis."

ENERGY VALUES OF FOOD.

THE Director of Publicity of the War Office has forwarded us a copy of a volume[1] prepared by Dr. R. H. Plimmer containing tabulated analyses of all the ordinary foodstuffs. So comprehensive a series of analyses has never before been published in this country, and the figures will no doubt be accepted as standards in the United Kingdom.

Dr. Plimmer is so well known and careful a worker that his analyses will carry the weight to which they are entitled. They comprise the usual estimations of water, ash, protein, carbohydrate, and fat, and the corresponding energy values expressed per 100 grammes, per ounce, and per pound. So far as gross values are concerned it is doubtful whether the labour involved in the collection of such an enormous amount of analytical data is justified. We think the publication of this volume represents only part of the story, for no serious consideration is given to the all-important presence or absence of accessory food factors, although it is true that the appendix contains a list, taken from the Medical Research Committee's report, which expresses qualitatively the presence, either singly or collectively, of the three vitamins in the common foodstuffs.

In this matter of the energy value of foods we need to be clear-headed. It is no longer possible to regard food values from the calorific standpoint alone; the vitamin content is probably a factor of even greater importance. At present all we can do is to determine the presence or absence of accessory food factors by actual feeding trials, and until our technique is vastly improved and we have reliable quantitative methods, the natural instinct which man has for a varied diet will continue to play its part. Dr. Plimmer rightly points out that the significance of the presence of the anti-rachitic vitamin in butter, margarine, dripping, and lard should not be neglected. It is present in butter, probably in dripping, but not in lard. Margarine made from vegetable fats, which represent the bulk on the market, is deficient in the anti-rachitic vitamin, whilst the other type of margarine, which contains the olein fraction of animal fat in order to make the consistency of the product he has received warm and sincere congratulations. Mr. Teale's career has, indeed, been a remarkable one. The son of a distinguished father, who was surgeon to the General Infirmary at Leeds, he was himself appointed surgeon to that institution in the year 1864. He increased the reputation of the hospital and of the medical school, and in an unobtrusive way he always stood for what was highest and best in professional conduct, though no man was less bound by rules; it was the underlying spirit that dominated his conduct. Mr. Teale's zeal in promoting education, his pioneer work in sanitation, and especially his original methods of popularising the knowledge of this branch of science, are known to all. Among the more formal congratulations which reached Mr. Teale was one from the Council and Senate of the University of Leeds which was presented in person by the Vice-Chancellor, Sir Michael Sadler. In a congratulatory letter Mr. Teale's services are happily referred to. From it we quote as follows: "We thank you for your sympathy with the young; for your alert and resourceful counsel; and, above all, for the example of your life. Your colleagues and friends of more than one younger generation join in cordial and grateful greetings to you, who, though the oldest among us, are still young in heart and mind." On the day following his birthday Mr. Teale was entertained to tea at the infirmary by the board and the Faculty.

---

[1] Analyses and Energy Values of Foods. By R. H. Plimmer, D.Sc., Captain attached to the Directorate of Hygiene, War Office. H.M. Stationery Office, 1921. 6s.

Mr. Teale was elected to the staff in the year 1864, the same year that saw the beginning of Sir Clifford Allbutt's and Mr. C. G. Wheelhouse's connexion with the infirmary. It was owing to the willing coöperation of these three men that opportunities were afforded to the younger men in Leeds who were desirous of devoting themselves to medicine or surgery to become connected with the infirmary; and by a self-denying ordinance they agreed that the new rule, which set a time-limit of 20 years for service on the full staff, should apply to themselves. This rule was associated with the provision that, when a member of the staff is, at the end of his 20 years' service promoted to the consulting staff, he retains the right to the use of six beds, and we are glad to note that this is a privilege which has been largely exercised. Mr. Teale, therefore, is still on the consulting staff and has the right to the use of six beds. The gathering at the infirmary was of a very informal but delightful character; there were no speeches, but Mr. and Mrs. Teale received the congratulations of their many friends; two photographic groups were taken, one of the general company which included the board and some medical men who had been especially invited as representing the profession of Leeds, and one of the honorary staff of the infirmary in which, of course, Mr. Teale figured as the oldest member. It is pleasant to record that Mr. Teale retains much of his old alertness of mind and manner; it is little more than two years ago since he gave the introductory address to the University Medical Society, and the students to who it was delivered were delighted and surprised with his charm and vigour. During the last session of the Leeds and West Riding Medico-Chirurgical Society he gave a paper on the subject of lithotrity, an operation which has probably been by no one more deftly performed than by Mr. Teale. Truly "those whom the gods love die young," but it is for this reason—that they never grow old.

MEDICAL COUNCIL FOR THE CARE OF SICK CHILDREN. On the invitation of the medical board of the Royal Liverpool Children's Hospital a meeting of physicians and surgeons specially interested in the institutional care of sick children took place in the board room of the hospital on July 1st. It was unanimously agreed: "That this meeting constitute itself the Medical Council for the Care of Sick Children of Liverpool and District." Thereafter an executive committee was appointed, and subcommittees were formed, to which the following subjects were referred: (1) the development of increased efficiency through coördination in the care of sick children; (2) after-care; (3) institutional care of sick babies; (4) research and post-graduate

CONFERENCE ON INFANT WELFARE.

UNDER the auspices of the National Association for the Prevention of Infant Mortality and the National Baby Week Council, a three-day Conference was held at the Central Hall, Westminster, on July 5th to 7th. Judging by the sustained attendances and the enthusiasm, the subject evoked very wide interest. On Tuesday the proceedings opened with an address by the President, the Right Hon. Viscount ASTOR. Sir GEORGE NEWMAN, who was to have presided at this Session, was about to take part in the sittings of the League of Nations at Geneva, which prevented his presence.

An Anti-Waste Conference.

The PRESIDENT said no one would be sorry that the nations of the world were foregathering periodically to discuss matters of importance, such as public health; it must mean a great benefit to the world at large. The issue of the moment was, quite rightly, economy; but it was equally necessary to save every single baby's life. It depended on the parents and others whether a child, when it grew up, would be a producer of wealth, or whether, conversely, it would be a cost and a charge on the community. Let the gathering resolve itself into an anti-waste conference, and let its message to the world be that it was out to prevent loss of all child life due to preventable causes. The recent coal strike was estimated to have cost the country 250 millions sterling; it was very difficult to get the country to recognise the indirect cost of ill-health. The Health Insurance Act statistics showed that the total cash benefits paid for sickness and disability amounted on an average to 14 million working weeks lost in a year. Put in another way, there were 270,000 persons unemployed owing to ill-health for the whole year. Also, there were a million children of school age so physically or mentally deficient that they were unable to receive the full benefit of the education provided. It was said that too much was being spent on education; the cost of education ought not to be reduced, but every effort should be made to see that the children were able to get full value from the education offered. The President proceeded to deal with public health services, including slum clearances and the provision of means of recreation for both children and adults. The question of venereal disease was a very difficult one; it touched morality, sex, the social life of the community, but work in connexion with it should not be neglected because of these things. Turning to the question of milk, he said the country consumed too little milk: the average amount consumed—by men, women and children—was ¼ pint per day. The Committee over which he presided found that in the winter, when the supply was reduced, if each child had the amount of milk it required, there would be none left for adults. If milk were a transparent instead of an opaque fluid, it would be much more easy to ensure a pure supply. A glass of milk often hid a multitude of sins. He did not believe there was any likelihood of increased efforts to ensure a pure milk supply resulting in a reduction of the supply. A clean universal supply of milk could only be brought about by general education. Turning to maternity and child welfare, there was, he said, an awakening of the world conscience on this matter; it was recognised that here was the foundation of the work of the countries of the world. There was no wish to break up the home, or to relieve any mother of her sense of responsibility; the desire was to make her feel to an increasing extent her sense of responsibility to her children. The President referred also to the school medical services and their satisfactory growth. In the presence of such a complexity of Governmental intrusion into the life of cities he appealed for a continuance of voluntary effort. In conclusion, he said the public was apathetic largely because the victories of preventive medicine were unseen; it was the failures which were apt to be seen. We did were permanent, but in which the reactions on turning, or those on progressive movement, were retained, anatomical investigation showed that the otoliths had been completely removed by the centrifuge, while the semicircular canals and the *cristæ* were found intact. The authors conclude that the tonic reflexes are mediated by the otoliths while the turning reactions and the reactions on progressive movements are discharged by the semicircular canals. These views are opposed to the older view of Mach and Breuer that the sensations and reflexes of progressive movements—for example, acceleration of movement—are determined by the otoliths.

ANNUAL REPORT OF THE NATIONAL PHYSICAL LABORATORY.

THE annual report of the National Physical Laboratory for 1920 indicates an ever-widening range of activity. The section of chief medical interest is that devoted to radiology (p. 49) under the direction of Dr. G. W. C. Kaye. The British radium standard of about 30 milligrammes of hydrated radium bromide has been supplemented by two other specimens which allow of accurate measurements of single quantities up to 120 milligrammes. For testing larger quantities it would be of advantage were a bigger working standard available. The two existing methods of measurement are being supplemented by a third one, elaborated by Madame Curie—namely, an ionisation method involving the use of the quartz piezo-electrique—with which the French school has long been familiar and adept. The examination of materials used in the construction of X ray apparatus is now carried out on a routine basis and will be welcomed by manufacturers who wish to have a guarantee of the effectiveness of the protective materials they use in their outfits. The Sabouraud pastille has been put through an exhaustive series of experiments to see how far it may serve as a measure of the dose of X rays received by a surface. If the X rays used are not of very short wave-length the pastille emerges from these tests with a very fair amount of credit. Different batches of pastilles, however, are apt to vary in their sensitiveness, and for this reason it is advisable that a sample from any new batch should be tested before reliance can be put upon the probable sensitiveness of the whole batch. The investigation is being extended to pastilles other than the original Sabouraud. The definition of X ray tubes is of great importance in radiographic work; the rough classification, fine, medium, or broad focus, serves at the present time, and tests of X ray tubes are carried out on these lines. It may be anticipated that the work of this section will increase in the future if the general recommendations of the X Ray and Radium Protection Committee gain general approval and adoption.

THE UNKNOWN ÆTIOLOGY OF INFLUENZAL PNEUMONIA.

ONE of the most comprehensive surveys of the problems of influenza yet published has just been issued by Gade's Pathological Institute in Bergen. The author, Dr. K. Skajaa, frankly admits nescience of the central problem, but he is able to throw many instructive sidelights on the epidemiology of the disease and the part played by secondary infection. Answers from general practitioners to an enquête sent out by Gade's Institute brought out some instructive points. In no case had any abnormal prevalence of pneumonia been observed after the influenza itself had subsided. This is one of the many points Dr. Skajaa makes in connexion with his argument that influenzal pneumonia is due to the unknown virus of influenza, and not to such microbes as streptococci and pneumococci. In several of the 184 necropsies made at the institute on persons dying of influenza the bacteriological examination of the lungs was negative. It would seem that uncomplicated influenzal infection of the lungs determines a serous and hæmorrhagic effusion which gives rise to diffuse, smooth consolidation. From this stage onwards the germs of mixed infection may play a subsidiary part, although the virus of influenza itself continues to influence the course of the disease. To emphasise the importance of the virus of influenza in determining the outbreak and course of influenzal pneumonia, Dr. Skajaa refers to three cases which occurred at the same time and in the same place, and which could be traced to the same source of infection. The condition of the lungs was identical in each case; below a horizontal, clear-cut line of demarcation there was a consolidated area which on section was seen to be smooth, shining, and almost black. The veins in every case were distended with clotted blood. So far there was nothing to distinguish one case from the other. But the bacteriological examination showed pneumococci in the first case, hæmolytic streptococci plus Pfeiffer's bacillus in the second, and streptococcus mucosus in the third. Pfeiffer's bacillus, it would seem, could not once be found at Gade's Institute during the first two waves of the recent pandemic, and in the later waves it was not found more often in the subjects of influenza than in healthy persons. Serological examinations also failed to associate any specific antibodies with Pfeiffer's bacillus, and its relation to influenza may now be regarded as even more problematic and doubtful than that of streptococci and pneumococci. With reference to immunity conferred by an attack of influenza, the conclusion is drawn that it is effective but of comparatively brief duration, being appreciably greater after a year than 18 months. As for susceptibility, underfeeding seems to play no part, and the tendency for influenzal pneumonia to break out in several members of the same household is traced to massive infection in overcrowded and insanitary quarters. Of the cosmopolitan diseases, such as plague, cholera, and small-pox, which have periodically devastated the world, influenza alone remains absolutely unbridled, rejoicing, as it does, in a sinister immunity to the restraining influences of civilisation.

THOMAS WHARTON JONES.[1]

Thomas Wharton Jones, pioneer in physiology and ophthalmology, teacher and quaint character, has been missed out of the "Dictionary of National Biography." Fairly full obituary notices appeared in *The Lancet* and *British Medical Journal*, and a compilation from these sources forms part of the "Roll" of the Fellows of the Royal College of Surgeons of England, now in accessible MS. in the College Library. Still, Sir Rickman Godlee's careful and interesting biography is welcome of one whom the scientific world has too readily forgotten.

Thomas Wharton Jones was, indeed, a giant in science, the teacher of Huxley and Lister, a man to reckon with. Born in 1808, in Scotland, he retained to the last the strong Scottish accent of his mother, though his father was of Welsh and English descent. He received his medical education at the University of Edinburgh, and became assistant to Robert Knox, the anatomist, with whom he shared in the odium visited on the Edinburgh anatomical teachers at the time of the Burke and Hare murders in 1829. After various wanderings he arrived in London in 1838, and was appointed lecturer on anatomy, physiology, and comparative anatomy at Charing Cross Hospital. He held this post till 1851, when he became first Professor of Ophthalmic Medicine and Surgery at University College. In 1881 he retired, and died at Ventnor on Nov. 28th, 1891. During the period from 1838 to 1881 he established the reputation which he had already made before coming to London. In 1835 he "was one of the

In the absence of Mr. Nathan Straus, his paper advocating pasteurisation of milk was read by Dr. S. G. Moore.—A paper on Milk in its Economic Aspect by Prof. R. Stenhouse Williams and Mr. J. Mackintosh was then read, calling attention to the present discrepancy between the summer and winter prices of milk, in contrast with the almost flat all-year-round rate obtained before the war.—Mr. F. Arnold Lejeune followed with a paper on The Production of Clean Milk from the Consumer's Point of View, in which he outlined a scheme by which a company concentrating on clean milk production might at once make a fair profit and render a public service.—A paper on The Supply of Milk to Expectant Mothers, Nursing Mothers, and Infants was read by Dr. E. W. Hope (Liverpool), who emphasised the need for providing milk to infants whose mothers were unable to suckle them. The points made in the discussion can be summarised as follows:—

Dr. H. Scurfield considered that we, as a nation, consume too little milk, and he pointed out its great importance as a food, especially in regard to its vitamin content. With some members of the medical profession the potential dangers of milk loomed so large that they discouraged its use. The slogan should therefore be, "Pure milk and safe milk"; hence the aims of the National Clean Milk Society should receive large support. Pasteurisation, as so often carried out in this country, was a farce, and therefore, in the result, a fraud. Dried milk was safe in regard to tuberculosis, and the drying process left the anti-rachitic vitamins intact. The public could largely protect themselves by using a home pasteuriser.—Dr. S. G. Moore (Huddersfield) emphasised the points made by Dr. Scurfield, and hoped that farmers would rise to the importance of supplying plenty of pure milk.—Dr. W. G. Savage (M.O.H., Somerset) declared the milk-supply of the country was no better now than 20 years ago. There were only two driving forces to bring about a better milk supply: (1) legal compulsion; (2) to make the production and supply of clean milk worth the while of those concerned. Dirty milk was dear at any price. He pointed out that milk which had been pasteurised was more dangerous when allowed to stand than was raw milk, because so many of the protective lactic acid organisms had been killed out by the pasteurisation.—Dr. F. E. Wynne (M.O.H., Sheffield) considered that fresh, or alleged fresh, cow's milk was an entirely unsuitable medium of nutrition for either adults or children. It was an economic absurdity to give so much attention to transporting vast distances a fluid which was 88 per cent. water; and scientifically it was bad because it presented the consumer with a first-class culture medium for bacteria. He urged the use of dried milk in preference.—Dr. C. W. Saleeby compared, unfavourably to the British, the physique of Americans with our own, and spoke of the much larger proportion of milk consumed in the States. Milk was a unique food, and it should be produced and consumed in far larger quantities by everybody.

Many other speakers, including Mr. W. Buckley and Mr. Tustin as representing the dairy industry, took part in the discussion and a resolution was carried urging the Government to proceed with the Milk and Dairies Bill and to make provision for further regulations therein.

Dr. A. Dingwall Fordyce (Royal Liverpool County Hospital for Children), speaking with regard to the sources of milk for babies, considered an advance had been made beyond the pre-war tendency to think that many difficulties in connexion with infant welfare would be solved if only there could be a clean milk supply. The problems to be faced were that of the best food for the baby and that in connexion with over frequent pregnancy. If the State provided food for babies it should obtain the best possible, and that was not cows' milk in any form, but mothers' milk. A certain number of mothers could not nurse their own babies, but a large number with milk had no babies to give it to, and for the purpose of allowing the right milk to be provided it was quite easy to discover whether another mother was disease free. He considered that welfare centres were going back in their educational work by providing such a large amount of proprietary food for infants.

Dr. J. C. Drummond (Lecturer in Physiology, University College, London) dealt with the subject from the physiological point of view, and Dr. Harold Waller (Medical Officer, Royal College of St. Katharine, Poplar) spoke from the biological aspect.—Dr. Cecil L. Williams emphasised the peculiar value of the milk supplied by the child's own mother.—Miss Breckenhurst (American Committee for Devastated Areas of Northern France) pointed out that directly the children in those areas had been taken in hand and given milk, either cows' or condensed, or dried, they had immediately increased in weight. It was generally admitted that there was much more infant mortality in the poor districts of large cities than in those parts where diet was more carefully studied and more milk available.—Miss Morson (Malvern) blamed the doctors for recommending patent foods to the poorer mothers, and the welfare workers for encouraging the sale of dried milk and other preparations, and Dr. Mills (Philadelphia Hygienic Association) in urging the absolute necessity of breast-feeding, condemned the bottle as being the cause of the increase in enlarged tonsils and adenoids.—Miss Batt (Health Visitor, Chelmsford) thought that worry had a very detrimental effect on the secretion of milk, and urged doctors and welfare workers when dealing with the failure of a mother to supply milk to aim at trying to discover whether their patient had worry of any sort.

Wednesday Evening Session.

Dried Milk.

On Wednesday evening, July 6th, a Special Medical Session, organised by the Society of Medical Officers of Maternity and Infant Welfare Centres, under the Chairmanship of Dr. Flora Shepherd, met to discuss the Uses and Abuses of Dried Milk, the subject being introduced by Dr. Scurfield. He thought that nothing but good would result from the more extended use of dried milk, whether for young children, expectant and nursing mothers, invalids, or adults of all ages. As there was no grade A milk to be had, and as pasteurisation gave little or no security at present, he regarded dried milk as the only safe milk on the market. He did not suggest that any milk, however obtained, was suitable for drying; it should always be taken clean from healthy well-fed cows. The only danger of the abuse of dried milk was that some ignorant person might think dried milk from cows, being so easily digested, was an adequate substitute for the milk of the human mother, and it was the business of all infant and maternity centres to counter that danger.

Dr. R. C. Jewsbury thought the first ideal to aim at was the breast-fed child; secondly, to breast-feed and supplement with modified fresh milk brought to the boil; thirdly, to feed the child on a modified unsweetened condensed milk in preference to dried milk. At present they were somewhat in the dark as to the effect of drying on the vitamins in the milk, but he had seen cases of rickets in children who had been fed on dried milk, and it was probably because they were getting fat in insufficient quantities.—Dr. Clarke (Baby Hygiene Association, Boston, U.S.A.) gave details of records kept with regard to about 6000 artificially fed babies, which went to show that children fed on dried milk put on more weight than those fed on other forms of milk.—Dr. Eric Pritchard thought they were all agreed that one of the most important elements in correct physiological feeding was the adjustment of balance and provision against excess, especially of the nitrogenous protein constituents. In his view weight was no guarantee as to the successful feeding of children.

As the outcome of further discussion Dr. Harold Waller moved a resolution recommending infant welfare centres to resolve that the tins containing such as that suggested by J. E. Burns: 10 per cent. thorium nitrate in 50 per cent. solution of citrate of soda. Naturally where infection is suspected the precautions must be redoubled.

OVARIAN HYPERNEPHROMATA.

SINCE the appearance in 1883 of Grawitz's original paper on the derivation of the common type of malignant renal blastoma, much attention has been directed to the neoplastic potentialities of aberrant suprarenal tissue. On histological and embryological grounds, Grawitz maintained that the renal hypernephromata were derived from groups of cells of the adrenal cortex which had become displaced from their normal environment during development, and although his views have been challenged from time to time, they continued to carry weight until comparatively recent years. Gradually the belief has gained ground that the origin of the renal hypernephromata must be sought for in the kidney itself, but the controversy has left its traces in a good deal of erroneous pathological teaching. The recognition of the occurrence of suprarenal rests, or accessory suprarenals, in other situations than the kidney, and the belief, supported by the authority of Cohnheim, that such rests might be expected to be peculiarly liable to neoplastic phenomena, led naturally to the search for hypernephromata elsewhere, and it was not long before this search was crowned with apparent success. Hypernephromata were described in the liver, the ovary, and elsewhere, and many pathologists taught that this type of neoplasm was fairly common in many situations other than the kidney. There is no doubt, however, that this somewhat fantastic pathology was accepted without a sufficiently critical consideration. It is certainly no longer possible to regard all the renal hypernephromata as being derived from accessory adrenals. On histological evidence alone this view is untenable, and the observations of Bulloch and Sequeira and of Glynn on the true suprarenal hypernephromata is very strong evidence against the Grawitzian theory. These authors have clearly established the fact that tumours of the suprarenal cortex are associated with alterations in the secondary sexual characters, changes which are not seen in patients suffering from renal tumours of the Grawitz type. Scrutinised in the light of this histological and clinical evidence, grave doubts must be thrown upon the diagnosis of hypernephromata in other organs. In the liver, for example, it is doubtful whether more than three or four true examples of this variety of tumour have been recorded; nearly always the apparent hepatic hypernephromata may be regarded as liver-cell carcinomata. Similarly, another origin than that from rests of displaced suprarenal cells must be sought for to explain the so-called hypernephromata of the ovary. In a valuable communication,[1] Prof. Ernest Glynn subjects the recorded instances of ovarian hypernephromata to a critical examination, reaching the conclusion that probably all of them are of lutein origin, and not at all related to the suprarenal gland. He points out that though suprarenal tissue occurs in the broad ligament, as it does in the vicinity of the testicle, no undoubted example of an accessory adrenal has ever been recorded actually within the ovary or the testicle. Again, though there are pronounced differences between the true suprarenal hypernephromata and the ovarian tumours, the latter correspond very closely to the accepted examples of luteomata recorded in the literature. And, finally, suprarenal virilism, the appearance of changes in the secondary sexual characters, does not occur in association with the ovarian hypernephroma. Prof. Glynn would seem to have proved his case fairly conclusively, and has delivered another blow at a theory which has for some time outlived its usefulness.

THE GOLD MEDAL OF THE ROYAL SOCIETY OF MEDICINE.

THE Council of the Royal Society of Medicine made on July 6th, at the annual general meeting of the Fellows, the first award of its gold medal to Sir Almroth Wright, K.B.E., C.B., F.R.S., in recognition of his valuable services to medicine during the recent war. The medal is the gift of the late Dr. Murray Leslie, and is to be awarded triennially on St. Luke's Day for original discovery in medicine and other allied sciences, or for the practical application of the results of previous investigations of other scientists, or for the most valuable contribution in any other way towards the progress of the art and science of medicine, preventive medicine, or surgery. The medal, a photograph of which is here reproduced to full size, was designed by Mr. E. Carter Preston, the well-known numismatic artist. The obverse represents Hygieia, daughter of Æsculapius, bestowing a wreath upon Research, represented as a kneeling figure holding a lamp. The inscription round the rim is "Auspiciis Societatis Regiae Medicinae," in exergue the motto of the Society, "Non est vivere sed valere vita" and, in field, "Institutae MDCCCV." The reverse represents Cheiron teaching Æsculapius the art of healing; beneath the centaur appears the serpent of Æsculapius. In the field to the left is the bow of Apollo (father of Æsculapius), symbolising the sun, the deliverer from plagues. The fountain on the right suggests the fountain of truth, and the inscription runs "*Finis Coronat Opus.*" The presentation was made by Sir John Bland-Sutton, President of the Society. Dr. C. T. Hagberg Wright received the medal on behalf of his brother, who is at present abroad.

Obverse. Reverse.

MR. PRIDGIN TEALE.

Mr. Pridgin Teale celebrated his ninetieth birthday on June 28th. From the members of his own profession, from the University of Leeds, and from other public bodies with which he has been so long associated and from many members of the general public, had a guarantee, given reasonably good economic conditions, of an early reduction in the proportion of the C 3 population.

---

[1] A Comparison between Ovarian "Hypernephroma" and Luteoma and Suprarenal Hypernephroma, with comments on Suprarenal Virilism, Journal of Obstetrics and Gynæcology of the British Empire, Spring, 1921

Mrs. HOOD voiced the views, through a coöperative women's guild, of over 50,000 working-class women when she urged that they should, first of all, consider the welfare of the mother from which the welfare of the child would follow. It was not a bit of good telling a working man's wife that she must stay a fortnight in bed if she was not provided with the wherewithal. She much regretted the great shortage of midwives, especially in view of the fact that panel doctors were not taking confinement cases. If midwives were given a proper status, better remuneration, and a chance of progressing, the supply would soon increase. In conclusion she advocated the provision of home helps for working-class mothers, so that whilst they were obliged to remain in bed after confinement their minds should be free from worry as to household matters. The ideal would, of course, be for working-class women to go into maternity homes or hospitals, but they would have to be educated to it.

Dr. NASH, in urging that the husbands should also be educated, said the hardest worker in the world, and one who knew no trade union eight hours' day, was the working man's wife with a family of children, and the sooner that fact was hammered into the trade union husband the better.—Mrs. BRACKENBURY said that women were learning what was necessary, and would soon find the courage to voice their needs in no uncertain voice, whilst Mrs. FOWLES emphasised the necessity of welfare workers getting into touch with the expectant mothers.—Miss BEVAN (Liverpool) stressed the necessity for coöperation and economic spending, and thought if they were to cut down expenses in regard to welfare work they might look into the expenditure on day nurseries; Miss LEE (Matlock Bath) pointed out the great importance of ante-natal visits in country districts.

Dr. SCURFIELD, in closing the discussion, thought when it could be said that everything that was possible was being done to prevent rickets, bad teeth, and to secure nose-breathers, then all else would follow and the nation could then be classed A 1.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Organisation of the Medical Profession in Ireland.

FOR many years past the organisation of the medical profession in Ireland has been unsatisfactory, and there has been no permanent body able to speak for the profession as a whole. The Irish Medical Association and the British Medical Association exist side by side, each with a membership of about 600. As many members are common to both bodies, probably not more than 900 medical men in Ireland—roughly one-third of the entire number—subscribe to any medical association. Since 1914 the British Medical Association has kept up a branch office in Dublin with a whole-time medical secretary, and Irish medical affairs are to a large extent under the autonomous control of the Irish Committee of the Association. Since neither of the two associations is sufficiently representative to warrant its speaking on behalf of the profession as a whole, it was found desirable in 1913, in the middle of the struggle over the Insurance Act, to form a third body with a broader basis of support in the profession. The Irish Medical Committee, formed by representatives of several local medical committees, and therefore representative of the profession at large, reports annually to a meeting of delegates of the entire profession, and it has received the support of both of the associations previously mentioned, whose secretaries act as honorary secretaries to the Committee. The Irish Medical Committee gained much kudos by its successful work for the profession during the Insurance Act struggles some years ago, and its constitution merits full confidence, but unfortunately it has no funds at its disposal and is dependent on the generosity of a few individual subscribers and on the assistance of the two associations for its existence.

It has long been felt that such a multiplication of bodies concerned with identical interests was uneconomical and unsatisfactory. Two years ago, therefore, the three bodies appointed a Joint Organisation Committee in an attempt (1) to organise the entire medical profession of Ireland into one body; (2) to establish some form of alliance or affiliation between such a body and the British Medical Association. Up to the present little progress has been made in these directions. The political and social condition of Ireland, in addition to rendering travelling and absence from home dangerous or unpleasant, has so occupied all minds as to prevent any constructive medical work. Moreover, before the British Medical Association could recognise such a body as is proposed its constitution would have to be altered, a step which would probably require much deliberation. It is hoped in certain circles that such amendments in the constitution of the British Medical Association may be framed as will meet not only the needs of Ireland, but the wishes of certain overseas branches of the Association. With this view in mind a conference was held at the offices of the Association last week between the Council and representatives of Ireland and the colonies, and certain proposals will be under the consideration of the forthcoming representative meeting at Newcastle-on-Tyne.

Grants to Irish Hospitals.

The Chief Secretary to the Lord Lieutenant of Ireland was asked in the House of Commons recently whether he could state for what period of years the Irish hospitals (or some, and which, of them) had been receiving out of public funds the sum of £16,000 per annum or what other sum; and whether during that period any equivalent grant had been made out of such funds to Scottish or English hospitals. Sir H. Greenwood replied that the grants to Dublin hospitals from the Imperial Exchequer originated in a clause of the Act of Union which bound the Parliament of the United Kingdom to continue certain grants made by the Irish Parliament for the maintenance of institutions for charitable purposes. These grants had been paid by the Irish Parliament to the following hospitals which are still in existence—namely, the Hospital for Incurables, the House of Industry, and the Westmoreland and Meath Hospitals. The Irish Parliament had also contributed generously to the construction of the Rotunda Hospital. The United Parliament, said the Chief Secretary for Ireland, became bound to continue these grants for a period of 20 years, but a far wider view of the contract has been taken, for in fact the grants have been continued to the present day and extended in number. The amounts paid to the hospitals have varied from time to time but were finally fixed at their present figures by the Select Committee on Irish Estimates, 1834, and modified by the Report of the Royal Commission of 1859. Neither English nor Scottish hospitals have directly received similar grants, nor have any Irish hospitals outside of Dublin received them.

Royal College of Physicians of Ireland.

At a meeting of the President and Fellows, held on July 7th, Sir James Craig, the President, announced the award of the Harry Godfrey Massy-Miles Prize to Dr. George Edward Strahan, who was a former student in the school of the Royal College of Surgeons and served during the war as Surgeon Sub-Lieutenant in the Royal Navy, was mentioned in despatches, and received the Distinguished Service Cross in recognition of his work. The prize was established in memory of Captain Harry Godfrey Massy-Miles, M.C., R.A.M.C., a licentiate of the College, who died in 1918 of wounds received in France, by his widow.

not want to see the failures, which became evident when epidemics occurred. This country could not afford to lose the progress and the gain in knowledge achieved during the past years, and he was sure those present would feel as a result of the Conference renewed courage and enthusiasm.

Maternity Homes.

DR. JANET CAMPBELL (of the Ministry of Health) read a paper on Maternity Homes, which we publish in our present issue.

Miss BEAVAN, of the City Council, Liverpool, spoke of the restrictions on this work imposed by municipal economy, and asked what factors in the work should be placed first in importance.—Miss CAMPBELL replied that the right course was to cater for the average mother and the average baby. No great improvement in midwifery service could be expected to be brought about unless in-patient accommodation could be provided where treatment would be available. If adequate salaries could be offered, she did not doubt that more women of education could be induced to take up this work; the need was easily demonstrated. She spoke of the accommodation already available for venereal cases.

Provision for Blind Babies.

Miss WALKER FINLAY, herself afflicted in the same way as those for whom she pleaded, spoke well and eloquently on this subject.—Dr. ERIC PRITCHARD highly praised Miss Finlay's work at "Sunshine House," the home for blind babies at Chorley Wood, Herts. So many of these little inmates were "not wanted" children and had been so badly neglected when they reached the home, that there did not seem much prospect of improvement, but in a short time astonishing progress was noticed.

Dr. C. J. MACALISTER spoke on the Residential Treatment of Ailing Children, and Dr. HOWARD GLADSTONE on the Value of Wards for Ailing Children.

AFTERNOON SESSION.

The afternoon session was presided over by Dr. CLARK, representing the United States National Health Department. He expressed the high appreciation of the Government he represented of the invitation sent by the Council. He also represented the American Public Health Association, which consisted of more than 2000 medical officers of health and others interested in public health problems; likewise he was spokesman here for the American Hygiene Association, a well-established body for the prevention of infant and maternal mortality. In America there was lacking, as yet, the degree of coördination in this work which he had found in this country.

Provision for Unmarried Mothers.

A paper on this subject was read by Mrs. CYRIL SMITHETT, in the course of which she said that though the increase of illegitimacy during the war had not been so great as was expected, since the war there had been a decided augmentation due to relaxation of discipline among girls and lack of parental influence. These unmarried mothers were very glad to accept the help offered them, and there was not nearly enough room in the homes of the National Council for the Unmarried Mother and her Child.

The discussion on this subject hinged chiefly on the means of enabling these mothers to support themselves and their children after leaving the home, and to discovering the male parent and compelling his support. Dr. E. H. T. NASH, of Isleworth, contended that these unmarried mothers were not, as a whole, immoral; and he urged a broad and much more tolerant spirit on the question.

Poor-law Accommodation for Mothers and Infants.

A paper on this subject was read by Miss M. E. BROADBENT, who described the value to the community of the lying-in wards of Poor-law institutional maternity wards during the war, when lack of housing and hospital accommodation created difficulties.

The principal discussion following this paper turned upon a question as to the systematic treatment of the eyes of the newly-born to prevent ophthalmia neonatorum. The CHAIRMAN spoke of the universal requirement in America for the instillation into the eyes at birth of a solution of nitrate of silver.—Dr. H. SCURFIELD said there was no such uniform requirement in this country, and that the practice varied in different parts.—Mr. C. W. GODBERT spoke of the thoroughness with which this matter was dealt with in Manchester, in close association with the eye hospital of that city.—Dr. NASH pointed out the requirement for cleansing the child's eyes contained in the Midwives Act, and the necessity placed on the holder of the C.M.B. certificate to notify to a doctor the occurrence of a discharge from the child's eyes. He also spoke of the provision for the treatment of syphilitic cases without public revelation.—The CHAIRMAN said that Dr. Williams of the Johns Hopkins University Hospital, in the States, kept an accurate record of 10,000 consecutive pregnancies which occurred, taking the period from the seventh month of gestation to the second week after birth, and he found, by an examination of the placental and other fœtal tissues that 26 per cent. of the deaths were due to syphilis. He emphasised the importance of intensive treatment of the syphilitic mother before the birth of the child in producing an apparently normal baby.

Residential Provision for Mothers and Babies.

A paper on this subject was read by Miss J. HALFORD, who described the different means of provision made in municipal maternity homes and in those run by voluntary agencies, and also in convalescent and rest homes for mothers and babies. A fortnight's stay in the latter was all the holiday some mothers ever got. Homes for babies only, both well and ailing, were also dealt with; Miss Halford pointed out that if more of the right kind of foster mothers were available, and if regular medical inspection at Infant Welfare Centres was supplied, this expensive institutional care could be superseded.

Miss Halford, after reading her paper, proposed the following resolution:—

> "That closer provision than at present obtains be exercised by the State and local authorities over all institutions which take children of under school age for payment."

It was seconded by Miss MAWSON.

Miss VANCE (St. Pancras) thought a society should be formed for the registration and closer inspection of foster-mothers. Much of the inefficiency of a particular type of foster-mother was due to inadequate payment and the lack of inspection.—Dr. MILLS (Philadelphia), in a breezy and humorous speech, advocated a "Fathers' Day," as such a large proportion of fathers were thoughtless and selfish on these matters, and did not realise what was due to the mothers in bringing up their children. He had addressed men in his city on the subject, where many people willingly received mothers into their families during an important period. The resolution was carried unanimously.

Dr. B. E. POTTER proposed:—

> "That this Conference is of opinion that a great deal of unnecessary loss of sight is still being caused by the failure to secure adequate preventive measures and prompt skilled treatment for ophthalmia neonatorum, and urges the Ministry of Health to institute an inquiry into the causes of such failure."

Mrs. RUSSELL (St. Pancras Board of Guardians) seconded, and it was unanimously adopted.

WEDNESDAY MORNING SESSION.

Under the chairmanship of Dr. JANET LANE-CLAYPON, the Conference discussed

The Supply of Milk: Its Physiological and Economic Aspects.

At the commencement a telegram from the Commissioner of Health, Chicago, was read, as follows: "In Infant mortality, average ten years 1907–16, before pasteurisation of milk, 116. Average four years since pasteurisation, 95·5. Diarrhœa and enteritis under two years of age, rate 134 per 100,000 population, before pasteurisation, 100 since."

arteries. But if the contraction is sufficiently severe and intense, as in a case of profound shock, fluid escapes from the vascular system, pressure in the arterioles falls, and this fall of pressure extends, quickly or slowly, but surely from the arterioles to all the vessels in proportion to the loss of fluid.

Prof. Bayliss and the Medical Research Committee teach that in the state of shock the capillaries dilate, the blood collects in them as in a sponge, and therefore the blood pressure falls. Dr. Hill and Dr. McQueen assert that in shock the capillaries are "choked with concentrated blood." But surely capillaries choked with concentrated blood, especially if they are also dilated, should cause a red or blue discoloration of the tissues, whereas in a state of uncomplicated shock the tissues are characterised by extreme pallor. Prof. Bayliss writes that "the colour of the skin in white races is almost entirely due to the blood in the capillaries. When these are empty of blood the tissues are white and cold."[1] From this it seems a direct conclusion that in the pale tissues of shock the capillaries are not dilated.

The main argument that the capillaries dilate in shock is stated as follows by the Medical Research Committee: "If in wound shock the lost blood is not in the arteries, and probably not to a great extent in the veins, it must be mainly stagnant in the capillaries."[2] With all due deference to the very great authority behind these reports, I submit that this is not a conclusive argument. Fluid may, and there is abundant evidence that it does, pass out of the vascular system and to a great extent out of the body in the state of shock, leaving the capillaries with all the other blood-vessels contracted and the tissues pale.

I am, Sir, yours faithfully.

London, July 11th, 1921. JOHN D. MALCOLM.

PSYCHOTHERAPY.

To the Editor of THE LANCET.

SIR,—In answer to Sir Bryan Donkin's remarks in your issue of July 9th upon my article Post-War Neurosis, may I be permitted to make two observations:—

1. I did not confuse psychotherapy with psycho-analysis, either intentionally or unintentionally. Having practised hypnotism and suggestion for many years before psycho-analysis, I am well aware of the mass of work done in the field of psychotherapy apart from psycho-analysis. A book like Dr. Ernest Jones's "The Treatment of the Neuroses" is sufficient to expel ignorance on this point. In italicising some of my statements Sir Bryan Donkin has been tempted by his bias against psycho-analysis to overlook the careful wording of my remarks. Using my own italics, I insisted upon "the importance of the sex factor as *a* cause of psychoneurosis," and said further that "it is the recognition of the sex factor which enables us to deal with *such a* neurosis in a satisfactory manner, and effect a proper cure by means of psycho-analysis."—

2. As a matter of fact, all I tried to show in my article is that there is the danger of under-estimating the significance of sex, especially in such cases as are labelled "Post-War Neurosis," and I tried to prove it by giving some typical cases from my own practice.

Like all anti-Freudians, Sir Bryan Donkin of course admits—at least in theory—the validity of the sex factor as "a cause of mental and nervous disorders"; indeed, he finds nothing new in this. It is only when a psycho-analyst proceeds to apply the theory in practice that he demurs. Yet he himself says: "There is no doubt that in certain periods and certain circumstances the prevailing repression of the sex impulses leads to the establishment of some form of neuropathy or psychopathy." My own cases only tried to show this principle in its working. Sir Bryan Donkin goes on to say that "a great measure of 'repression' is the rule of custom in nearly all civilised countries. Yet neuropaths and psychopaths are still far from dominating any civilisation by their numbers." Just so! Freud has pointed out repeatedly that all civilisation is due to the repression of primitive impulses; but he was the first to show that it is the inability to "repress successfully" that causes the characteristic "conflict" of the neurotics (who do not necessarily form the majority of the population). If the time is not yet for Freud's view to be accepted as established truth, there is certainly no justification for proclaiming it confidently as "false psychology."

I am, Sir, yours faithfully,

Manchester, July 9th, 1921. S. HERBERT.

OPEN ETHER ANÆSTHESIA DURING THROAT OPERATIONS.

To the Editor of THE LANCET.

SIR,—The deep anæsthesia needed for tonsil dissection has been found by some a path rather overhung by brambles. As an anæsthetist and as a patient I yield to no one in praise of chloroform, but in these cases I am sure that ether or ethanesal is preferable, if a Grand Guignol of possible thrills is to be avoided.

I therefore welcome the publicity Dr. H. Sington gives to warmed ether by the description he publishes in THE LANCET of July 2nd of his apparatus. I designed and have used since six years a similar one. It was described and illustrated in the *Journal of the Royal Army Medical Corps* of February, 1919, and reproduced in an article I submitted at the Sixth Meeting of the Interstate Association of Anæsthetists at Pittsburg, and published in the *American Journal of Surgery*, Quarterly Supplement of Anæsthesia, January, 1921. This apparatus is now manufactured by Messrs. Coxeter.

I am, Sir, yours faithfully,

CHARLES T. W. HIRSCH,
Anæsthetist, Metropolitan Ear, Nose, and Throat
and Royal Ear Hospitals.

July 10th, 1921.

THURSDAY MORNING SESSION.

The conference reassembled on Thursday, July 7th, when Sir ARTHUR STANLEY presided.

Dr. HELEN MACMURCHY read a paper on *Inheritance and Environment as Factors in Racial Health.*

Dr. C. W. HUTT (M.O.H., Holborn) read a paper by Mr. F. I. HOFFMAN, of the Prudential Insurance Company of America, on

The Influence of Weather Conditions on Morbidity and Mortality in Early Infancy,

which resulted in an interesting discussion, in the course of which Dr. NASH and Mrs. LASSEY emphasised the importance of studying the effect of rainfall and of climatic changes on infants and young children.—Dr. CECIL WILLIAMS thought, so far as England was concerned, the great question to be considered in regard to babies was not so much infantile diarrhœa as respiratory diseases brought about by climatic changes.—Mr. SCOTT (Heston Urban District Council) considered that people's energies would be far better spent if they concentrated on removing slums and building better houses by not conforming too strictly to the requirements of the Ministry of Health.—Mr. GODBERT (Manchester) regarded infantile diarrhœa not so much due to heat as to other causes stimulated by the heat, such as the increase in the house fly and the resulting contamination of food, whilst Dr. DUNSTAN BREWER (M.O.H., Swindon) believed that the decrease of epidemics of infantile diarrhœa depended mainly upon getting into touch with earlier cases.

Dr. C. W. SALEEBY read a paper on the

Ante-Natal Factors of Life and Death,

which gave rise to a great deal of discussion. He described as the outstanding fact of infant mortality in the past decade in Great Britain to be the suppression of summer diarrhœa. Passing on to the arguments of the "better-dead" school of eugenists, Dr. Saleeby described the theory that infant mortality is an illustration of natural selection as baseless, completely breaking down even in the one instance—hæmophilia—which might be expected to illustrate it; and considered in turn the genetic, toxi-genetic, gestational, and obstetric factors of the problem.

Mr. JAMES STEWART (Glasgow) maintained that many difficulties did not arise through ignorance, but purely and simply owing to social conditions, and until such conditions were adequately ameliorated, and every mother had all that was necessary for the well-being and comfort of herself and her child, there would be no good done, even though they held conferences to eternity.—Councillor ANGUS MCDOUGALL (Subcommittee on Child Welfare, Glasgow) also emphasised the need of improved social conditions, and Dr. WYNNE thought the more successful they were in their endeavours in reducing infant mortality the more seriously would they have to contemplate what steps they were to take towards reducing the unregulated begetting of unwanted children.

Dr. SALEEBY, in replying to points raised in the discussion, observed that drinking amongst young mothers was a peculiarity of this country. As to improvement in social conditions there was nothing more tragic than a mother doing her maternal duty and breast-feeding her baby when she herself was badly nourished. The first charge on the State ought to be the mothers and the children of the country. We paid the Prime Minister and the Archbishop, why not pay mothers in order that they might properly do that for which they were fitted?

At the afternoon session Dr. GORDON LEY read a paper on a Comparision between Working-class Mothers and those of the Educated Classes from the Point of View of Difficulties Encountered in Pregnancy, Labour, and Lactation.—Miss MCCONNELL dealt with infant mortality in Poland, and Dr. J. H. SEQUEIRA read a paper on Syphilis as an Ante-natal Factor in Racial Health.

Mrs. SCHARLIEB, speaking with regard to Dr. Ley's paper, said there was a time when every mother suckled her own child, but there came evil days when both the doctors and the nurses encouraged mothers to think that it was undignified to nurse their own children, and that it would interfere with the regaining of their figures. She, however, thought that both nurses, doctors, and—most important of all—mothers, were realising that if the nation was to prosper and the infantile mortality to be reduced, the first duty of a married woman, blessed with a child, was to suckle it herself.—Dr. SCURFIELD thought less damage was done by the monthly nurse than by ignorant or slack doctors who did not realise what the baby lost by not being breast fed. But once every woman knew that she must feed her baby and was supplied with the proper amount of information, she would not be put off by any doctor. In his opinion a woman who refused to feed her baby was more a murderess than the woman who, in a state of frenzy, attempted to kill her child.—Dr. DUNSTAN BREWER (Swindon) said although they quite rightly blamed the monthly nurse and the doctor, there was someone else to whom blame could be attached—namely, the school teacher—who could do so much with young people. He had only discovered one thing which rendered mothers physically incapable of feeding their own children, and that was the destruction of the breast tissue.

Mrs. SCHARLIEB, speaking with regard to Dr. Sequeira's paper, urged that they should endeavour to bring about more coördination between the venereal clinics, the infant welfare, the maternity centres, and the tuberculosis centres, so that there might be a reduction of expense and increased facilities for the detection and treatment of venereal diseases. They were acting wrongly if they disregarded the serious warning Dr. Sequeira had given.—Mrs. NEVILLE ROLFE (National Council for Combating Venereal Diseases) hoped that infant welfare organisations would not shirk the question, for it was only with their aid that that very large group in the population, the respectable married woman, could be reached.—Miss AMY HUGHES thought quite young boys and girls should be educated as to the danger of venereal disease, for they were very apt to become infected and pass the disease on to their babies when married.—Dr. SALEEBY said unless the problem was better dealt with than it had so far been venereal diseases would become a deadly menace to the future of the race.

THURSDAY EVENING.

In the evening there was a meeting of the General Council of the Association of Infant Welfare and Maternity Centres for the purpose of discussing the most vital and essential forms of child welfare work.

Miss ZOE PUXLEY opened the discussion, and in doing so regretted the lack of coöperation between the workers in infant welfare centres, both official and voluntary, the main reason being the difference in outlook and point of view. Next came misunderstanding and suspicion, and then prejudice. She urged them to remember that the aims of their work were the things that mattered most, and they could only dimly approach the goal if they all pulled together. If they learnt to put themselves last and the work first the battle would be won. The game was more than the player, as the ship was more than the screw.

Dr. H. KENWOOD (M.O.H., Stoke Newington) said that in public health generally the real need of the hour was for more knowledge of the very simple laws of health. Whatever the baby was fed upon, the parents must also receive the mental pabulum, rendered easily assimilable—peptonised and humanised. In maternity and child welfare work, extended to the school age and followed by medical inspection among school children, they where he devoted all his attention to diseases of the eye. In a short time he acquired a large consulting practice. Still retaining the idea of becoming an academic teacher of physiology, he again became a demonstrator of this subject. During his demonstratorship in the University of Manchester Menzies carried out original work on the spectral and other characters of derivatives of hæmoglobin for which, from the University of Edinburgh, he, in 1894, obtained the degree of M.D. with first-class honours. Appointed lecturer in 1911 in the Medical School of Newcastle-upon-Tyne, first under Sir Thomas Oliver, he held this post with marked success until 1915, when, on the transference of Prof. F. A. Bainbridge to London, Menzies became professor of physiology—a post he held until his death. Besides his contributions on methæmoglobin, and the action of acids on the blood corpuscles, on the secretion of bile, on vision in children, the urine in the frog and the frog's kidney, Menzies' name will, perhaps, be best known by the popular and successful "Essentials of Physiology," published jointly with Bainbridge. Prof. Menzies leaves a widow and a daughter.

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Royal Leamington Spa.

Dr. W. L. M. Goldie points out at the beginning of his report for 1920 that the population of Leamington is exceptionally constituted. The town is a health resort, a residential district for retired persons, and a residential suburb for people who work in Coventry and Birmingham. There are no industries worth mentioning, and the population is mainly concerned in supplying the wants of residents and visitors. The estimated population for 1920 was 29,445, the recorded death-rate 13·04, and the death-rate corrected for the age and sex constitution of the population 10·83. The infant mortality rate was 62·5, the death-rate from pulmonary tuberculosis 0·30, and the birth-rate, as in other towns, showed a great increase on the previous year. In 1919 there were 456 births and in 1920 654, making a rate of 22·2, the highest recorded since 1888. Commenting on the infant mortality rate Dr. Goldie says: "It is a cause of regret that the infant welfare clinic up to the present time does not appear to have attracted those mothers in poorer circumstances to whom it might be thought advice as to the upbringing and feeding of their children would be most beneficial." A community like Leamington should afford an ideal opportunity for intensive child welfare work, helped by voluntary workers. The borough also has its housing problem. For some years before the war, despite the increase of population, there had been a marked diminution in the number of houses annually erected; the shortage was estimated in 1919 at 529. To meet this need schemes have been sanctioned for the erection of 166 houses, a number obviously inadequate for the needs of the town. Vaccination is not fashionable in Leamington Spa. Out of 580 children born between July 1st, 1919, and June 30th, 1920, and alive at the latter date, only 20 per cent. were known to have been vaccinated.

West Gloucestershire United Districts.

The rural districts of East Dean, Gloucester, and Lydney, and the urban districts of Awre, Newnham-on-Severn and Westbury-on-Severn are dealt with in Dr. O. W. Andrews's report for 1920; the area covered is nearly 100,000 acres in the Forest of Dean, around the city of Gloucester, and between the Severn and the [illegible] The two most important industries are coal-[illegible] and tin-plate manufacture. The population [illegible] for 1920 was 41,314; a remarkable increase in the birth-rate is reported—from 19·3 in 1919 to 28·6 in 1920. The death-rate was 12·6 per 1000 and the infant mortality rate 57·2. The figures, it is pointed out, compare favourably with those for England and Wales, and it is doubtful if any other coal-mining district is able to show as low a rate for infant mortality. The housing problem remains unsolved, although substantial progress has been made in two portions of the district, more particularly in Gloucester Rural District, where 19 houses were actually completed in 1920 and 65 others were in course of erection. Work at the shipbuilding yards at Beachley and Chepstow caused a demand for houses, but the closing down of the yards has ended this artificial demand and houses are now only wanted for bonâ-fide residents. In the near future in the agricultural portions of the district the need for more houses is expected to become reduced, as more and more land is going out of cultivation on being converted into permanent pasture, and the demand for agricultural workers gets regrettably less. A separate report is included for each of the six districts, and that for East Dean contains an interesting note on the maternity and child welfare work carried out during the year by the Cinderford Mothers' Club and Babies' Welcome.

Corrigendum.—In the notice of Bootle School Medical Service, which appeared in THE LANCET of June 25th, 1921, p. 1385, the second paragraph should have commenced as follows: In the year 1920 there were 3687 routine and 2264 special inspections, while 5808 re-examinations were made; and since the inauguration of school medical inspection in 1908 there was an average attendance of 11,424 children, &c.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual meeting of the Fellows of the College was held on July 7th, for the election of four members of the Council. Sir Anthony Bowlby, the President, was in the chair. 923 Fellows voted, and of these seven were personal votes. Three voting papers were spoiled. The result of the voting was as follows:—

	Votes.	Plumpers.
H. J. Waring	415	3
F. F. Burghard	410	2
C. H. Fagge	353	47
W. T. Thomas	331	34
L. B. Rawling	271	10
Victor Bonney	247	14
J. H. Fisher	214	31
R. J. Howard	193	17
A. H. Cheatle	186	5
D. J. Armour	124	9
W. Turner	94	3

The President declared Mr. Waring and Mr. Burghard to be re-elected, and Mr. Fagge and Mr. Thomas to be elected, members of the Council. Mr. H. J. Price and Mr. Willmott Evans acted as scrutineers.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the annual meeting of the metropolitan branch held on July 8th, Dr. W. H. Hamer, M.O.H. Administrative County of London, was elected president of the branch for the forthcoming session.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The following have been admitted as Fellows of the Faculty:—

Charles Cameron, M.B., Ch.B.; Charles G. A. Chislett, M.B., Ch.B.; James P. Crawford, M.B., Ch.B.; Lachlan Grant, M.D.; James L. Gregory, M.B., Ch.B.; Robert Kennedy, M.D., D.Sc.; David D. Logan, M.D., D.P.H.; and James E. Middlemiss, M.R.C.S., L.R.C.P.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR THE DIPLOMA IN DENTAL SURGERY.

Kenneth George Hyland, Evan Elwyn Lewis, and John Christopher Leslie Phillips.

EXAMINATION FOR THE DIPLOMA IN PUBLIC HEALTH.

Correspondence.

"Audi alteram partem."

THE FÆCES IN ALIMENTARY DISORDERS.

To the Editor of The Lancet.

Sir,—In the *British Medical Journal* there has been an interesting discussion on the relative value of clinical and laboratory methods in the investigation of disease. The paper in your columns of July 2nd by Dr. Robert Coope on the "Fæces in Alimentary Disorders" supplies data for comment. As an expert laboratory worker on biochemistry Dr. Coope has found little help from the application of a Gram-stained bacteriological film in diagnosis. He has "found little help from it, and in our present state of knowledge it seems to me not worth while for clinical purposes to take time over it. It is another matter if definite bacteria are suspected, such as the typhoid group or tubercle." It is difficult to understand what the author means by the value of the application of Gram stain in the recognition of a typhoid organism, as this organism is, like *B. coli*, Gram-negative.

These statements are surely inaccurate and misleading. Clinicians who are in the habit of examining the stools by simple staining methods know that in many instances information is obtained from their use that is of much greater clinical value than that furnished by the other methods of examination described by Dr. Coope. The laboratory worker is by no means altogether to blame for the erroneous teaching for which he is sometimes responsible. The clinician has at least equal responsibility. The fault appears to lie in the tendency to excessive specialisation in research, and to the segregation of special laboratories for chemical pathology and for bacteriology away from the immediate proximity of the patient. The field of biochemistry and chemical pathology is considered big enough to fill the whole horizon of the worker. He is disinclined to attach importance to simple bacteriological questions on which he feels, rightly or wrongly, that he has little right to have an opinion. The real condition of affairs obtaining in the human tissues and excretions, one of interdependence of various factors concerned in normal and abnormal nutrition, is overlooked.

If Dr. Coope will coöperate with some of his clinical friends in making a Gram-stained film from the stools in a selected series of cases, careful attention being paid to the diet, the clinical condition of the patient, and the state of the urine, I venture to think that he will profoundly modify some of his teaching.

I am, Sir, yours faithfully,

Edinburgh, July 6th, 1921. Chalmers Watson, M.D.

X RAYS IN MALIGNANT DISEASE.

To the Editor of The Lancet

Sir,—The end results of surgery in some forms of malignant disease—notably, cancer of the uterus—are so far from being satisfactory that experiments in the way of a purely radiotherapeutic treatment are justified. And if X ray treatment is to take the place of surgery, it is certain that the dosage must be large, and, within certain limits, concentrated in time. I say within certain limits, because it is quite possible, and, in my opinion, likely, that a large dose spread over four or five days instead of being administered in one, would be as effective and less risky. It is, however, improbable that for some time to come, in this country at least, professional opinion will countenance non-operative treatment of cancer; and we thus have to consider what is the best method of applying X rays in conjunction with surgery. In the writer's opinion, it is not justifiable to subject patients to the double risk of a major operation and an enormous dose of X rays, which lessens their vitality for many weeks. Rather should we employ a technique which produces a definite improvement in health almost from the first. Such a technique we possess in the repeated medium dose method, which has now been used with success in cancer of the breast, and to some extent in cancer of the uterus, for at least a decade.

It consists in giving the patient, if possible, before operation a series of seven or eight sittings, extending over about a fortnight; and subsequently a course of ten or twelve sittings extending over a month, twice a year for two to three years. Indeed, when practicable, it would be desirable that the patient should have a course every year or eighteen months for the rest of her life—for the "cancerous tendency" remains, no matter by what method an individual growth has been removed. It may be true that a single medium dose excites the cancer cell to activity; of this I have no experience. But it is certain that a series of such doses produce rapid diminution, and even the disappearance, of any palpable cancer masses, if such are present; and in any case has a remarkably beneficial effect upon the physical energy and the subjective well-being of the patient. In making these statements I feel sure that I shall have the approval of nine out of every ten radiologists who have been treating breast cancer during the past ten years. No claim is made that cancer is "cured" by such methods, but courses of X ray treatment given after the manner described do enable patients who show definite recurrence when first seen to recover a fair degree of health, and often to live in comfort for many years. Although this form of treatment was commenced more or less empirically, it probably finds its rationale in recent experiments at the Rockefeller Institute in America, and by Professor Sidney Russ and his colleagues in this country—experiments which have shown that a series of comparative small doses of X rays raises on animals the resistance of the body to cancer implantation. Hence, to give such courses even when there is no ascertainable recurrence may be regarded as a proceeding analagous to preventive inoculations.

The same experiments have shown per contra that a large single dose of X rays reduces the body resistance; and there can be little doubt that, whatever happens to the original tumour, a similar fall occurs in the human subject, and is maintained for many weeks. The danger in cases where there are already existing metastases is thus very evident. It must also be remembered that in the year 1913, at the British Medical Association annual meeting at Brighton, Gauss of Freiburg described a treatment not very dissimilar to that now used at Erlangen; a few months later reports began to come through of severe skin lesions which had come on in some cases as much as a year after the cessation of the treatment.

The fact, on the one hand, that great benefit can be produced by a series of moderate doses, and, on the other, that the single massive dose, whatever its virtues, is not unaccompanied by dangers, will, I think, induce British radiologists, if and when they come to treat certain cancerous tumours by X rays alone, to seek some means of dividing the dose in a manner to minimise its ill-effects while producing an equally good therapeutic result.

I am, Sir, yours faithfully,

F. Hernaman-Johnson.

Harley-street, W., July 6th, 1921.

THE CIRCULATION IN SHOCK.

To the Editor of The Lancet.

Sir,—In The Lancet for July 9th Dr. Leonard Hill and Dr. J. McQueen assert that "the data of systolic and diastolic pressures in the main arteries so laboriously compiled is then information of little or no clinical value." May I be allowed to emphasise this point? The blood pressure in the large arteries is no index of the pressure in the arterioles or in the capillaries. Pressure may rise in the aorta and fall in the capillaries. Contraction of the arterioles tends to reduce pressure in the arterioles, and, in proportion to its intensity, cuts off the blood-supply from the capillaries. It also usually raises pressure in the large

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 12TH.

National Insurance Bill.

On the motion of the Earl of ONSLOW, the National Health Insurance Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 6TH.

Medical Staff of the Health Ministry.

Sir J. D. REES asked the Minister of Health whether the 32 doctors on £1000 a year, who were appointed by his predecessor, were still retained at his Ministry; and, if so, when he would dispense with their services.—Sir A. MOND replied: I presume my hon. friend refers to the Regional Medical Officers. If so, the answer to the first part of the question is in the affirmative. In answer to the second, I refer him to my statement on May 12th, introducing the Ministry of Health estimates, in which I made it clear that after personal investigation I thought that this staff does useful work, and should be continued. In any case, I am not in a position to dispense with their services except on the terms of their engagements.—Sir J. D. REES: Is not the right hon. gentleman examining the situation with a view to dispensing with their services as soon as their agreements allow, and has he inquired into the feeling locally where these gentlemen work as to the necessity for their appointment?—Sir A. MOND: As I have said, I have personally gone into the work of the officers concerned, and am satisfied that they are doing very useful work. In any case their period of service would not come to an end for several years.—Colonel ASHLEY: Are we really to understand that the Ministry of Health have tied themselves down for several years in the engagement of their public officials, and is that not a most extraordinary procedure?—Sir A. MOND: In view of the fact that most Government officials are engaged for life in the Civil Service I think that a temporary engagement for five years in an important office is not a very unreasonable agreement.—Colonel ASHLEY: Are Government officials never dismissed?—Captain COOTE: Is it not a fact that the public health has never been so good as it is to-day?—Viscountess ASTOR: Is not infant mortality going down?—No further answer was given.

Kinematograph Lights and Blindness.

Captain Viscount CURZON asked the Minister of Health whether the Committee on the Cause and Prevention of Blindness had as yet reported upon the question of the injury to eyesight resulting from the extreme power of lights used in film production; and whether any action was contemplated as a result.—Sir A. MOND replied: I have received the Report of the Committee referred to. Their conclusion is that there is evidence of only transient injury to the eyes having occurred in a few cases and that such injury was associated with the use of a particular open arc lamp without a proper screen. I have received an assurance from the Incorporated Association of Kinematograph Manufacturers that no member of the Association will permit any open arc lights to be used in their studios for general illumination without glass filters, and in view of this I do not consider further action necessary.

Licensing Reform.

Major KELLEY asked the Attorney General when he proposed to introduce a Bill incorporating the recommendations of the recent conference on the revisal of licensing restrictions.—Mr. SHORTT (Home Secretary) replied: My right hon. friend has asked me to reply. He hopes that the Bill may be introduced at the earliest possible moment, but it is not possible at present to be more definite.

Scottish University Grants.

Sir ROBERT THOMAS asked the Secretary for Scotland whether his attention had been called to the fact that on pages 271 and 286 of the Returns from Universities and University Colleges in Receipt of Treasury Grants, 1919–20 [Cmd. 1263], it was stated that the Universities of Glasgow and St. Andrew's received no grants from local authorities, and that in the statements of accounts on pages 274 and 288 of the same publication, it was shown that Glasgow University received £8700 and St. Andrew's University received £1500 in grants from local authorities; whether he would say which of these statements was correct; and whether he would say exactly from what source these sums of £8700 and £1500 were derived.—Mr. MUNRO: The headings on [illegible] 74 and 288 of the Return referred to are in my [illegible] somewhat misleading. In point of fact there are [illegible] made to the Universities of Glasgow and St. Andrew's from local rates. The sums mentioned by my hon. friend are annual payments made from the Local Taxation (Scotland) Account under the Education and Local Taxation Account (Scotland) Act, 1892, out of the Scottish share of moneys made available by Statute for relief of local taxation in the different parts of the United Kingdom. These payments to the Scottish Universities reduce the amount which might otherwise be distributed among local authorities in Scotland in relief of local rates, and therefore might be said to represent indirect contributions from the rates to the Universities.

An Epileptic Soldier's Treatment.

Viscountess ASTOR asked the Minister of Pensions whether he was aware that F. J. Horn, late Private No. 241,316, Devon Regiment, was ordered residential institutional treatment which he obtained at the Maghull Epileptic Colony, near Liverpool; that, owing to the death of his wife and to his having seven young children, he was obliged to leave the institution before his treatment was completed; whether the institution was prepared to readmit him, but he was unable to leave home, although his condition was becoming worse, as he could not obtain help under Section 9, Sub-Section (i) of the War Pensions (Administrative Provisions) Act, 1918; and whether, since he could not get an adequate grant from the United Service Fund, it was possible to give any further financial help.—Major TRYON replied: My right hon. friend is having immediate inquiry made in order to ensure that this man shall receive such medical treatment as is appropriate to his condition. With regard to the last part of the question, I would point out that if this man becomes an in-patient of an institution not only is he maintained free of cost, but a sum of 88*s*. a week (less any pocket money he may require) becomes available for his children.—Colonel C. LOWTHER: Does this mean that he will get outdoor relief?—Major TRYON: It is not a question of outdoor relief. It is a question of allowance paid by the Ministry of Pensions to the children of those who are under treatment for war disability.

Tuberculosis Statistics.

Mr. WIGNALL asked the Minister of Health the number of cases of tuberculosis for the years 1914–20, giving each year separately.—Sir A. MOND replied: The number of cases of tuberculosis notified in England and Wales in each of the years 1914 to 1920 is as follows:—

(A) Pulmonary Tuberculosis. (B) Other Forms of Tuberculosis.

Year.	(A)	(B)	Total.	Year.	(A)	(B)	Total.
1914	76,109	23,388	99,497	1918	71,631	18,942	90,573
1915	68,309	22,283	90,592	1919	61,154	16,357	77,511
1916	68,109	22,799	90,908	1920	57,844	15,488	73,332
1917	68,801	20,884	89,685				

THURSDAY, JULY 7TH.

Hastings Pensioners and Regional Director.

Mr. FREDERICK ROBERTS asked the Minister of Pensions if his attention had been drawn to the fact that a letter was forwarded to the Department from Hastings on June 23rd regarding the position of various pensioners in that town; whether he was aware that in reply the regional director stated that all cases were required to be dealt with in the first instance by the local war pensions committee concerned; and whether, in view of the fact that all the individuals had placed their cases before the local committee previous to the communication being forwarded, he would have inquiries made into the various cases concerned.—Mr. MACPHERSON replied: The answer to the first two parts of the question is in the affirmative. The fact stated in the last part of the question, however, had not previously been brought to notice, and in view of that fact I am now having further inquiries made. I will inform my hon. friend of the result.

Phthisical Pensioners and Widows' Pension.

Dr. M'DONALD asked the Minister of Pensions if a widow whose husband had died from phthisis within two years of discharge from the army, owing to debility, was entitled to a pension.—Mr. MACPHERSON replied: It is not possible to give a categorical answer to this question, as each case has to be considered on its merits. I may say, however, that it has frequently been found possible to award full pension to the widow when the husband's death has occurred in the circumstances stated.

Medical Examination of Pensioners.

Colonel NEWMAN asked the Minister of Pensions whether he would see that the assessment committees encouraged medical officers employed in the Ministry to get men who had recovered off the pension list and men who were permanently disabled and in a final and stationary stage on to the list for permanent pension; and was he aware of the grievance felt by men who were aware that they could

Obituary.

SIR GEORGE HENRY SAVAGE, M.D., F.R.C.P. LOND.,

CONSULTING PHYSICIAN FOR AND LECTURER ON MENTAL DISEASES AT GUY'S HOSPITAL.

Sir George Henry Savage, who died at his residence in Devonshire-place on July 5th, at the age of 78, was a recognised authority—perhaps the most widely known in the kingdom—on psychological medicine, a subject to which he had devoted a long and strenuous life from the time of his appointment as assistant medical officer to the Bethlem Hospital in 1872. The son of a chemist and druggist of Yorkshire stock he was born at Brighton in 1842, and after being educated at Brighton entered as a medical student at Guy's Hospital, where he subsequently won the Treasurer's Gold Medal. In 1864 he qualified with the M.R.C.S. Eng., obtained the L.R.C.P. Lond. in the following year, and also graduated M.B. at the University of London, proceeding to the M.D. in 1867. After holding house appointments at Guy's Hospital and at the Sussex County Hospital, and a spell of general practice in the north of England, he became house physician to the Royal Bethlem Hospital, a post which he held for seven years, a period which proved the turning point of his life. He took the M.R.C.P. while holding this appointment, being elected to the Fellowship in 1885, seven years later. In 1879 he was appointed physician-superintendent, occupying that position for 10 years, and his simple yet authoritative teaching attracted visitors from the United States, the colonies, and the continent, while he was in great request as a post-graduate teacher, particularly for the M.D. degree of the University of London. He also delivered systematic lectures on mental diseases to the students of Guy's Hospital, where he was physician for mental diseases.

For over 20 years he was consulting physician to the Royal Institution for the Mentally Deficient at Earlswood, which he visited almost regularly once a month, giving advice to the staff on points of detail, and taking the greatest interest in the patients, many of whom became warmly attached to him. His great literary capacities were mainly revealed in sporadic essays and addresses. He edited the *Journal of Mental Science* for some time, added largely to our conceptions of mental diseases by his practical knowledge, and enriched the literature of the subject with a sound manual and many addresses and lectures. In 1907 he delivered before the South-West London Medical Society the Bolingbroke Lecture, taking for his subject the Factors of Insanity, and in the same year the Lumleian Lecture before the Royal College of Physicians of London, his subject being the Increase of Insanity. Two years later he was appointed Harveian Orator of the Royal College of Physicians, when he delivered an admirable oration upon Experimental Psychology and Hypnotism.

He was at different times examiner in mental pathology at the University of London, and president of the Medico-Psychological Association. In 1912, the year in which he was knighted, he became the first president of the newly formed section of psychiatry of the Royal Society of Medicine.

J. T., a personal friend, gives the following intimate picture of Savage:—

By the death of Sir George Savage English medicine is the poorer for the loss of a great personality. Savage touched medicine at many points, although in his specialty he was *facile princeps*. His early experiences in general practice in Cumberland were no doubt a potent factor in evoking wide medical understanding and sympathy. His work there was exacting, often entailing 20 miles or more on horseback, but it gave him an experience which he himself always described as invaluable. When he came to Bethlem there were suspicions in some minds that mental disease was, in many instances, physical in origin, and Savage was one of the earliest to recognise and to insist upon, for example, that general paralysis was the result of structural changes in the nervous system. Those of us who had the privilege of going round with him at Bethlem can never forget his insistence on the dictum, "show me a case of general paralysis and I shall show you a case of syphilis." But to those who knew Savage intimately—a privilege which the writer enjoyed—the extraordinary width of his non-medical interests was a source of continual wonder. He had, for example, a remarkable collection of minerals, and the writer can never forget a memorable evening when he was taken to an upper room where he and his wife enjoyed a wonderful demonstration of his specimens, often with the graphic history of how he came by them, interposed. Sometimes they were the result of a descent into a coal or lead mine, sometimes a present from a grateful patient in Cumberland who knew that the "young doctor" was interested in curious stones, and sometimes they were an accidental find in the course of a long moorland ride to see a patient.

Savage was also a remarkably keen botanist. At a very early age he compiled, or assisted in compiling, a flora of Sussex and his interest in the flora of his native county, and, indeed, in all flowers, remained unabated. The writer once spent a happy afternoon with him at Shoreham hunting—unsuccessfully as it happened—for the *Trifolium stellatum*, which Savage had found there 40 years before! It is still there—an escape from the Levant through a wreck which occurred more than 100 years ago. But the afternoon was not wasted, for Shoreham is rich in many curious things, and Highdown Hill to which we went afterwards, as Savage demonstrated it, was a mine of treasures. To see Savage when he came to a place where something *should* be growing go down on his knees and push up his glasses or leave them hanging on one ear, was to witness the keen joy of the "seeker," and it was not often a seeker who sought in vain.

Savage touched life at so many points that he was always a delightful companion. He was an alpine climber of no mean achievement, and but for his deafness would have been President of the Alpine Club. He was a fisherman who fished with the dry fly for three years before he caught a trout, although he caught many afterwards, and he had done most things in sport and nearly all he had done well. But, after all, it was the man we all loved, the many-sided in his sympathy and understanding, the big-brained vigorous bodied man, with his rich intellect and his strong body who yet had time to think of "the little things that matter."

Sir George Savage married first, in 1867, a daughter of Mr. Jacob Walton, of Alston Moor; and secondly, in 1882, a daughter of Dr. H. Gawen Sutton, physician to the London Hospital. This obituary notice would not be complete without recording that Savage was, from the start of the movement to the end of his life, a consistent supporter of the cause of medical education for women.

JAMES ACWORTH MENZIES, M.D. EDIN., M.A. DUNELM,

PROFESSOR OF PHYSIOLOGY AT DURHAM UNIVERSITY COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

THE death of Dr. James Acworth Menzies—professor of physiology at Durham University College of Medicine, Newcastle-upon-Tyne—on July 8th, at his brother's residence in Luton, brought grief to numerous friends, for he was beloved by all who had the privilege of his acquaintance. Dr. Menzies was a son of the Rev. R. Menzies, of Riding Mill, Northumberland, and he married a daughter of the eloquent and outstanding Rev. Alexander Maclaren, D.D., of Manchester. After studying medicine at the University of Edinburgh, where he qualified M.B. and C.M. in 1890, he was appointed demonstrator of physiology in the University of Manchester, a post which he held until 1906. Menzies endeared himself to all—colleagues and students alike—who came in intimate relation with him. Patient and untiring in his devotion to the interests of his students and to his department, Menzies proved himself a genuine and eminently successful teacher, who soon attracted and retained not only the respect but even the love of his pupils. Never was anything a trouble to him where the interests of students were concerned.

Circumstances determined him to quit for a time—but it was only for a time—the pursuit of physiology, and he turned to ophthalmology, acting during 1896–97 as house surgeon of the Royal Eye Infirmary, Manchester, and as a successful consultant in Rochdale permanent pensions, which was the most important point of policy in the Bill, he proposed to make the fourth year after the man's discharge the date at which a man should be finally examined for permanent pension. It was in the interests both of the disabled men and the State that the machinery of the Ministry should be reduced as soon as possible to its minimum, so that within a measurable time all that would be left would simply be a system of regular payments through the Post Office. The present system with its periodical examination of men involved an elaborate structure of medical boards, referees, and so forth. The medical machinery of the Ministry had hitherto involved the employment by the Department for whole-time or part-time of one man in every four or five of the medical population of the country. The periodical examination of disabled men and officers meant annually the equivalent in working time of a strike of 20,000 men. But more important than all was the effect that finality would have on the mind of the man who had been harassed by medical boards and the relief he would feel at getting away from the atmosphere of the war and its disabilities. But there were insuperable obstacles in the way of granting a great many permanent pensions. Where a case was clear, such as in the case of amputation, he gave permanent pension, but any other permanent pensions which he gave now meant a one-sided process. A pensioner if he got worse could come back and get an increased pension, but if he got better the Minister had no right of appeal. The fixing of four years after discharge had been arranged under the advice of the Government actuary. If a medical board when examining for final pension was satisfied that a man might get worse he proposed to instruct them not to make the award permanent, so that the man might get the benefit of the doubt.

He also proposed to set up an independent appeal tribunal, composed not of a lawyer, an ex-Service man, and a doctor, as at present, but of two doctors (one of whom would be president of the court), an ex-Service man, and an officer. Any discharged man would have the right to be examined in the fourth year for permanent pension by this independent tribunal. On a conservative estimate he hoped to save £2,000,000 a year in administration alone. If a man became seriously worse after his permanent pension had been given to him he (Mr. Macpherson) still retained the right which he had under Article 6 of the Royal Warrant, and even if the claim had been finally settled a man would be entitled to hospital treatment and to certain allowances, and those privileges he would retain for the rest of his life. The Ministry might have said to the men who left the Army without medical examination that they could not go into their claims for pensions afterwards, but they had not done so, and under Article 9 they had given a right to every man who had served in the British Army, even though he had not been examined on discharge, to come before a medical board and have all the rights of a man who was examined at the time of his discharge. The House would realise that that was a privilege which could not be open to all men always. He had decided to fix the limit for appeal at seven years after service. If they did not have a final limit of that kind they would have to keep up permanently the medical boards, the appeal tribunals, and all the paraphernalia with which the Ministry was associated. The independent tribunal which was in existence now had the right to hear all cases of discharged men, but he was asking the House in this Bill to place a time-limit on the right of appeal of six months, because otherwise the pensioner would become forgetful, papers would be lost, and they would find that the man's disease, if he had a disease, was changed, and all sorts of conditions would be superinduced. In Subsection (2) of Clause 5 he was making it quite clear what procedure was necessary in order to effect a right judgment in any appeal case. In Clause 6 he was taking the same power of commuting the disability pensions of seamen and marines as he had already in the case of soldiers and airmen. In regard to Clause 7 there were some boards of guardians which objected to the Minister of Pensions being the guardian of an orphan of a soldier or sailor. Of course, he could not get back from boards of guardians cases of epilepsy and imbeciles, but he was taking powers to get those children whom the Ministry could take charge of under its control. He would listen to any reasonable amendment to the Bill in Committee, but naturally he would stand by the principles which he had endeavoured to set forth.

In reply to Colonel ASHLEY, Mr. MACPHERSON said that as a conservative estimate the economies in administrative expenses resulting from the doing away with the 800 committees would be anything from £6,000,000 to £12,000,000.

Mr. LAWSON, in moving the rejection of the Bill, explained that he did so in no hostile spirit. The Labour Party did not really desire to see the Bill thrown out, but wanted to call attention to the financial and administrative powers of [illegible] committees. The Minister proposed to reduce local [illegible] to the same position and degree of impotence [illegible] old-age pension committees. He was opposed [illegible] limit for permanent pensions.

Mr. C. EDWARDS, another Labour Member, seconded the amendment.

Major ENTWISTLE supported the Bill and urged that it was not a measure to set up a new bureaucracy. The bureaucracy was there already; the only question was whether they should be controlled by the local committees or by the Ministry who supplied the funds.

Colonel F. E. FREMANTLE, after narrating personal experiences of the fraudulent methods which had been employed for the securing of pensions, commented warmly on the fact that out of 21 members of the Departmental Committee there was not a single medical man. He added that while it was quite right for the State to obtain finality, if it should prove that in 10 or 20 per cent. of the cases finality was unfairly secured, it would be a serious matter. He pointed, for example, to the recurrences occurring in mental cases and in tropical diseases, such as malaria. He asked for provision to be inserted under which final awards should be subject to reconsideration in ten years' time.

Major TRYON (Parliamentary Secretary to the Ministry of Pensions), replying to the debate, pointed out that the medical question was one of great magnitude. At the present moment there were 125,000 officers and men on the hands of the Ministry for treatment as the result of wounds or sickness. It was not altogether realised that this task had been put on the Ministry quite lately as the result of the transfer of wounded and sick from the Navy, Army, and Air Force on demobilisation. Lieut-Colonel Fremantle's proposal that final awards should be liable to revision after ten years would mean the resurrection of the whole machinery of medical boards, &c., which they were so anxious to get rid of. He did not think that such a suggestion was in the interests of the pensioners or of economy.

The second reading of the Bill was agreed to without a division.

Drunkenness Statistics.

Sir J. D. REES asked the Home Secretary the number of convictions for drunkenness which occurred during the first 26 weeks of 1921 in the City of Carlisle where direct control of the liquor trade was in operation, and in the remainder of the areas scheduled by the Central Control Board (Liquor Traffic) in England and Wales, together with the figures for the corresponding period of 1920.—Mr. SHORTT replied: I understand that complete figures on all the points raised by the hon. baronet are not available. But the following table with which I have been supplied covers the main points on which he desires information:—

Convictions for Drunkenness in Carlisle and the Rest of the Scheduled Areas of England and Wales.

—	23 weeks 5th Jan.–13th June, 1920.	23 weeks 3rd Jan.–12th June, 1921.
Carlisle	44	72
Rest of scheduled areas of England and Wales	41,309	32,224

MONDAY, JULY 11TH.

London and the Water Shortage.

Viscount CURZON asked the Prime Minister whether, in view of the present shortage of water and of the fact stated in the press that there was only three weeks' supply of water remaining for the metropolis at the present rate of consumption, it was the intention of the Government to take such action as would compel economy generally in the use of water during the present shortage.—Sir A. MOND replied: I have been in constant communication with the Metropolitan Water Board in regard to the great need for economy in the use of water in consequence of the continued drought, and the steps taken by the Board have resulted in an average daily reduction in the week ending July 1st of 37 million gallons below the figure for the corresponding period last year. This is due largely to the assistance of the press and the ready coöperation of the public. I shall not hesitate to take further action to compel economy should this be necessary.

Medical Boards and Disability Pensions.

Rear-Admiral SUETER asked the Minister of Pensions whether the medical boards had had instructions from the Ministry of Pensions to cut down disability pensions by 10 to 20 per cent.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: No, Sir. Nor is there any prospect of my right hon. friend being induced to attempt economy by such means, as he has already made it abundantly clear that he will be no party to the issue of any such instructions.

Blind and Paralysed Ex-Service Men.

Mr. HANNON asked the Minister of Pensions the number

ARTIFICIAL LIMBS FOR PENSIONERS.—The Minister of Pensions has appointed a Committee to inquire into the arrangements for the supply and repair of the various types of artificial limbs, which are provided under the Royal Warrants and Orders in Council, and into the comparative advantages of the metal limb and the wooden limb; and to make recommendations thereon. The members of the Committee are: Sir Archibald Williamson, Chairman; Prof. A. F. C. Pollard; Major Maurice Sinclair, C.M.G., R.A.M.C.; Major M. P. Leahy; Major A. A. Atkinson; Sir Lisle Webb, Director-General of Medical Services, Ministry of Pensions; Mr. Frank Cecil Meech, ex-Corporal of Horse, Royal Horse Guards. Mr. W. J. Sullings has been appointed Secretary of the Committee.

VOLUNTARY HOSPITALS COMMISSION.—The following nominations to the Voluntary Hospitals Commission have now been made:—

The Earl of Onslow (Chairman), Lord Clwyd, Captain W. E. Elliott, M.C., M.P., Sir Robert Hudson, G.B.E., and Mr. D. O. Malcolm, nominated by the Minister of Health.

The Marquess of Linlithgow, nominated by the Secretary for Scotland.

Sir Napier Burnett, K.B.E., M.D., nominated by the Joint Committee of the British Red Cross Society and the Order of St. John of Jerusalem.

Sir Cooper Perry, M.D., F.R.C.P., nominated by King Edward's Hospital Fund.

Mr. H. Wade Deacon, C.B.E., nominated by the British Hospital Association.

Sir John Rose Bradford, K.C.M.G., M.D., nominated by the Royal College of Physicians.

Sir George Makins, G.C.M.G., F.R.C.S., nominated by the Royal College of Surgeons.

Dr. R. A. Bolam, O.B.E., nominated by the British Medical Association.

The remaining member will be nominated by the Scottish Committee of the British Medical Association, whose nomination has not yet been notified. Mr. L. G. Brock, C.B., Ministry of Health, has been appointed Secretary to the Commission.

GREAT NORTHERN CENTRAL HOSPITAL OF RECOVERY: SUMMER FÊTE.—On Saturday last the Princess Royal accompanied by Princess Maud, opened the Hospital of Recovery, which is charmingly situated at Grovelands Home Park, Old Southgate. The Princess Royal inspected a number of patients who were lying in beds in the open air, and afterwards went through the wards of the hospital. Short addresses were delivered, amongst others, by Sir G. Lawson Johnston, treasurer, and Mr. G. B. Mower White, senior surgeon to the hospital, who remarked that the cost of new accommodation was substantially reduced by the system of transferring less serious cases from the main hospital to the present building. A feature of the entertainment provided was the Maypole dance and country dances by children, trained by Miss Sayer, of Finchley, in aid of the children's ward balcony, while the band of the Coldstream Guards played during the afternoon and evening. At present 45 beds are occupied at Grovelands, but this number can be increased to at least 70 when sufficient funds are forthcoming. The Hospital of Recovery was presented to the Great Northern Central Hospital by the Southgate Voluntary Aid Organisation, and was used during the war as a hospital for wounded soldiers.

METROPOLITAN HOSPITAL SUNDAY FUND.—The following are among the amounts received at the Mansion House. The total to date is £70,000.

FEDERATION OF MEDICAL AND ALLIED SCIENCES: ANNUAL REPORT.—The report for 1920–1921, issued by the Executive Council of the Federation, opens with the statement that the Federation was registered on March 29th last under the Companies Acts as an Incorporated Association. The Council claims on behalf of the Federation, which has now completed the second year of its existence, a considerable advance towards true representation of the members of the medical and allied professions—an advance which, despite the hampering effect of present high prices and limited financial resources, permits a hopeful outlook for future success. The past year is described as memorable for the introduction of legislative measures involving radical changes in the conduct of the health services of the country. The voluntary hospital system and the independence of private practice have been threatened; prodigal schemes for the coördination of medical services have failed, but rather because of national poverty than because of any united action on the part of the professions affected. Those professions are now awakening to the necessity of fuller participation in the councils of the nation. The bringing of moderate and reasoned views to the notice of those responsible for the formative stages of legislative measures, rather than the application of criticism at a later stage, has been the aim of the Council, and much of the useful work thus performed is not immediately apparent. Amongst other activities in this direction may be mentioned the assistance given to the Medico-Psychological Association of Great Britain and Ireland in support of certain amendments to Clause 10 of the Ministry of Health Miscellaneous Provisions Bill, and the memorandum and questionnaire sent to all constituent societies of the Federation on the subject of Clause 11 of the same Bill, which sought to establish municipal hospitals and authorise rate maintenance of voluntary hospitals. At a conference of the Federation, held on Nov. 5th, resolutions were unanimously adopted expressing regret at the introduction of health legislation involving important questions of principle in a Miscellaneous Provisions Bill; maintaining that the public interest demanded that the Minister of Health should consult collectively the medical, dental, pharmaceutical, nursing, and midwives' professions, and others concerned with public health; pointing out that the voluntary hospital system should now be supported by State aid, but that the system of patients' contributions towards their maintenance, and the attempts to link up voluntary hospitals with Poor-law infirmaries, should be given fair trial; and emphasising the necessity, in the event of the establishment of municipal hospitals, of clearly-defined representation of the professions concerned on all bodies responsible for the administration of such hospitals. The support of the Federation was also sought by the British Dental Association in the introduction and passage of the Dentists Bill in Parliament. The Council was asked to express an opinion regarding the new panel record cards, and advised a fair trial of the latter. The Draft Regulations, issued under the Dangerous Drugs Act, 1920, engaged the attention of the Council; the views of the constituent societies were obtained concerning certain clauses, and representations were thereupon made to the Home Secretary and incorporated in the amended regulations now issued. Amongst other details of internal organisation of the Federation, the nucleus of a "citizens' council" has been formed to provide the Federation with a body of representative lay opinion on matters of public health. With a view to discussing means of coöperation with certain bodies not represented in the Federation, a conference was arranged on Feb. 1st, 1921; the Royal Colleges, the British Medical Association, the Society of Medical Officers of Health, the National Medical Union, the Medico-Political Union, and the Federation were invited to send delegates. The four last-named bodies accepted and attended the conference, which adopted resolutions urging the medical profession to concentrate its efforts and speak with one voice when the need arises, and expressing the opinion that the only method at present available for such concentration of effort is a federation of representative bodies. No medical candidates have stood for Parliament during the year; the Council has interviewed two prospective candidates, and has in mind the possibility of a general election. Various associations have been elected to the Federation, and one society has withdrawn. Sir Berkeley Moynihan had consented to be elected the first President of the Federation on its incorporation, and Sir Malcolm Morris (Chairman of the Executive Council during the past two years) was at the same time elected the first Vice-President. The offices of the Federation are shortly to be transferred to more suitable premises, where a conference hall will be available. The Council has decided to publish a weekly paper devoted to the national aspect of the work of the medical and allied professions, and a subcommittee has been appointed to make the arrangements.

Post-Graduate Course on Infant and Child Welfare.

A Course of Twelve Practical Demonstrations on the Management and Feeding of Infants and Young Children by Dr. E. Pritchard to Qualified Practitioners.

TUESDAY, July 19th.—10.30 A.M., Demonstration XI., Rickets, Causes, Symptoms, and Treatment.

THURSDAY.—3 P.M., Demonstration XII., The Feeding of Children between 9 months and 2 years.

VOCAL THERAPY SOCIETY.—On Saturday, July 9th, at the West End Hospital, St. Catherine's Lodge, Regent's Park, a competition concert was given by the King's Services Choirs, which consist of ex-Service singers in and out of hospital. The work of the Vocal Therapy Society, under whose auspices the concert was held, is the endeavour to restore physical and mental health to ex-Service men suffering from loss of speech, mutism, stammering, stuttering [illegible] resulting from war injuries or shell shock. The [illegible] Society is at 27, Grosvenor-place, S.W.1.

Notes, Short Comments, and Answers to Correspondents.

MATERNITY HOMES.[1]

By Dr. Janet M. Campbell,

SENIOR MEDICAL OFFICER, MINISTRY OF HEALTH.

THE Ministry of Health have now recognised between 60 and 70 maternity homes in England and Wales, with about 700 beds, and some 20 proposals for new homes are under consideration. This is in addition to maternity beds found in homes for unmarried mothers, and to old-established maternity hospitals and Poor-law lying-in institutions.

The Need for Maternity Homes.

The great reduction in the infant mortality-rate which has taken place during the past 20 years has not been accompanied by a corresponding lowering of the maternal mortality rate, as is shown by the following table:—

Year.	Birth-rate.	Death-rate.	Infant mortality-rate.	Maternal mortality ‖ (Classification as in use before 1911).			
					Deaths per 1000 births.		
				No. of deaths.	Sepsis**	Other causes.	Total childbirth.
1905	27·3	15·3	128	3905	1·87	2·33	4·20
1906	27·2	15·5	132	3757	1·75	2·27	4·02
1907	26·5	15·1	118	3520	1·60	2·23	3·83
1908	26·7	14·8	120	3361	1·48	2·09	3·57
1909	25·8	14·6	109	3379	1·56	2·14	3·70
1910	25·1	13·5	105	3191	1·42	2·14	3·56
1911	24·3	14·6	130	3236	1·52	2·15	3·67
1912	23·9	13·3	95	3299	1·47	2·31	3·78
1913	24·1	13·8	108	3271	1·34	2·37	3·71
1914	23·8	14·0	105	3469	1·63	2·32	3·95
1915	21·9*	15·7†	110	3210	1·56	2·38	3·94
1916	20·9*	14·4†	91	3038	1·47	2·40	3·87
1917	17·8*	14·4†	96	2446	1·39	2·27	3·66
1918	17·7*	17·6†	97	2353	1·35	2·20	3·55
1919	18·5*	13·8†	89	2852	1·76	2·36	4·12
1920	25·4	12·4	80	3942‡	1·87	2·25	4·12

* Based upon populations specially estimated for this purpose.
† Based upon civilian deaths and estimated civilian population.
‡ Subject to slight alteration.
‖ Excluding deaths not classed to pregnancy and childbearing, but returned as associated therewith.
** Including phlegmasia alba dolens.

Note.—In the Registrar-General's Annual Report for 1920 the birth-rates and the death-rates, 1911–1920, will be based upon revised estimates of population made after the results of the next Census become available. The rates in the Registrar-General's Report may differ, therefore, from those in the above table.

In 1900 the infant mortality-rate was 154 per 1000 births and the maternal mortality-rate 4·8, the total number of maternal deaths due to pregnancy and childbearing being 4455. In 1920 the infant mortality-rate had fallen to 80, but the maternal death-rate was 4·2 with 3942 deaths. During the earlier years of the century there was a slight though fluctuating improvement in the maternal death-rate, 3·5 per 1000 births being the lowest figure reached. In 1919, however, the Registrar-General reported that puerperal mortality was higher than for any year since 1905 and that the increase was *preponderantly due to sepsis.* This was sufficiently arresting, but it is still more disquieting to learn that in 1920 there has been no decrease in the maternal death-rate, which remains, as in 1919, at 4·12 per 1000. The death-rate from septic infection in 1919 was 1·76, but in 1920 it was still higher, being 1·87, the same rate which obtained in 1905. In other words, in spite of our modern knowledge of the causes and prevention of infection, of the successful application of this knowledge to the practice of surgery, and of the elaborate training given to medical students and nurses in surgical technique, we are, as regards midwifery, almost back in our old position at the beginning of the century before the Midwives Act was passed.

Most maternal deaths at the time of childbirth are preventable if proper facilities and reasonable skill are to hand, and deaths from septic infection should be rarely met with. Sepsis is almost invariably introduced from without by one or other of the attendants on the woman, the doctor, the midwife, or the handywoman. Every committee for examination, and of the fact that each examination entailed a substantial cost to the taxpayer.—Mr. Macpherson replied: I am aware of the facts stated, and I am entirely in sympathy with my hon. and gallant friend. I have, in fact, already anticipated his suggestion in the War Pensions Bill which is now before hon. Members, and which is down for second reading to-morrow.

---

[1] Abridged from a paper read at the second English-Speaking Conference on Infant Welfare on July 5th.

Appeal Tribunals.

Lieut.-Colonel Sir Frederick Hall asked the Minister of Pensions what was the number of cases awaiting hearing by the pensions appeal tribunal on March 31st and June 30th, respectively; whether, in view of the very important nature of their work, the appeal tribunals would sit constantly through the summer vacation; if so, what number; and how many of these would be in the London region.—Colonel Gibbs (Treasurer of the Household) replied: The number of cases awaiting hearing by the pensions appeal tribunals on the dates mentioned was as follows:—

—	March 31st, 1921.	June 30th, 1921.
Listed and in course of being heard	1134	3071
Outstanding awaiting listing for hearing	7734	6779
	8868	9850

Of the total number of cases awaiting hearing approximately 1000 are cases in which the appellants have already been afforded one or more opportunities of appearing before a tribunal. During the latter part of May and in June additional courts were set up and 1000 cases are now being dealt with each week. Further tribunals are in course of formation. Tribunals will sit constantly through the summer vacation. The number of tribunals to sit in August and September has not yet been arranged, but approximately 16 will sit during August and 12 during September. The number of tribunals to be allocated to London for the holiday period will depend upon the state of the work in London as compared with other regions.

International Health Organisation.

Sir J. D. Rees asked the Lord President of the Council if he would give the House some information as to the recently announced determination of the League of Nations to look after the health of the world, the manner in which this enterprise was to be conducted, and the probable cost to the taxpayers of this island.—Mr. Balfour replied: In pursuance of Articles 23 and 25 of the Covenant the League is proceeding, as it is bound to do, to set up an International Health Organisation. At the present moment the arrangements are in the initial stage only. Great Britain makes a lump sum contribution towards the expenses of the League, no part of it being ear-marked to particular branches of the League's work.

League of Nations and Typhoid in Poland.

Lieut.-Colonel Sir Frederick Hall asked the Lord Privy Seal how many countries belonged to the League of Nations; what was the estimated cost of maintaining the League for the current financial year; and what part of such cost would be borne by Great Britain.—Mr. Balfour replied: Forty-eight States are at present members of the League of Nations. The Budget of the League covers the calendar year, and for 1921 amounts to 21,250,000 gold francs, or, quoted in sterling, reckoning 20 gold francs to the £ about £1,062,500. Great Britain's contribution is approximately £52,000—the exact amount will depend on the rate of exchange current at the time that the instalments are made.—Sir J. D. Rees: Does the £52,000 include such benefactions as the money granted for dealing with typhoid in Poland or will that necessitate an extra budget?—Mr. Balfour: I think it is inclusive, but I do not think it includes what my hon. friend calls benefactions.

Financial Position of Irish Hospitals.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been drawn to the annual report of the board of superintendents of the Dublin hospitals issued last week; whether he was aware that the report stated that the board were satisfied that all the hospitals were conducted in an economical and thoroughly efficient manner, but that all were in a more or less critical condition financially; whether he was aware that the indebtedness of each hospital was as follows: Westmoreland, £7046; Meath Hospital and County Dublin Infirmary, £6688; Cork Street Fever Hospital, £5882; House of Industry Hospitals, £5843; Rotunda, £5014; Coombe, £1355; Royal Victoria Eye and Ear, £7500; Royal Hospital for Incurables, £7270; and whether he would take immediate action to have grants made to these and to other hospitals in Ireland out of the £500,000 which had been allocated for the relief of voluntary hospitals in the United Kingdom or an equivalent grant to relieve their financial difficulties.—Sir H. Greenwood replied: I am aware of the facts and figures disclosed in the report of the board of superintendents of Dublin Hospitals for the year ending March 31st, 1920, but in regard to the mode of relieving the financial condition of the hospitals I can only refer to my right hon. friend the Chief Secretary's reply to my hon. friend the hon. Member for Rathmines of June 30th last. The hon. Member's figures need a small correction in one item—namely, the figure of £7046 is that for Stevens Hospital, not for the Westmoreland Hospital. The latter hospital has, I understand, no deficit.

Pharmacists and Dangerous Drugs Act.

Mr. Alfred T. Davies asked the Secretary for the Home Department whether he was aware that the committee appointed to consider outstanding objections to the draft regulations issued under the Dangerous Drugs Act, 1920, after considering the claim that prohibition of retailing by pharmacists was ultra vires in view of Section 7 (2) of the Dangerous Drugs Act, and observing that the point could only be settled by a competent judicial authority, proceeded with their inquiry as if the contentions were not well founded; and whether he had since obtained, or proposed to obtain, the opinion of the Law Officers of the Crown on this contention of the pharmacists.—Mr. Shortt replied: The answer to the first question is in the affirmative; to the second, in the negative.

FRIDAY, JULY 8TH.

War Pensions Bill.

Mr. Macpherson (Minister of Pensions), in moving the second reading of the War Pensions Bill, said it was a measure for securing administrative economy, but not at the expense of any pensioner, for that was a policy to which he would never be a party. The number at present on the pension list was as nearly as he could make out 3,500,000 beneficiaries of all kinds. It was the unanimous proposals of the Departmental Committee, which he had appointed in December last to examine the large and intricate machine of pensions administration, which he was presenting in the form of a Bill to the House. These proposals he believed would be to the best interests not only of the taxpayer, but of the pensioner and of the State. The expenditure of the local war pensions committees out of public funds was over £20,000,000 a year, but the committees were virtually independent bodies over which as Minister of Pensions he had no control. That position was quite intolerable. The local committees had now drifted into an entirely false position. In 1917, when the Pensions Ministry was formed, the staff of the local committees amounted to 300; to-day it had grown to nearly 7000 and the voluntary workers were comparatively few. In nine cases out of ten the expenditure of the local committees was now left to the discretion of these paid officers, and the result was that there was laxity, and even fraud, in the expenditure. During the past seven months the Ministry discovered no fewer than 126 cases of fraud by officers. In these circumstances he thought he ought to be responsible for the appointment of those men. He proposed to reduce the number of the local committees from 1200 to not more than 450, thus getting rid of about 800, and effecting what he regarded as large economies. Under the new scheme there would be large areas of administration, each having at its centre an office with a war pensions committee attached to it. In some sparsely populated districts of the country, such as his native Highlands, it would be necessary to appoint only a local man as officer without a committee. The committees and the officers of the different areas would be directly under him as Minister, and he should feel himself responsible for the financial and administrative work of the offices. He hoped to appoint in each office a "soldier's friend" to give advice to ex-Service men in regard to pensions, a departure which in London had proved most valuable. The composition of the new committees would be substantially the same as it was now, but there would be somewhat different proportions of interests. Instead of one-half the representation of the local authority would be only one-fourth, for the reason that the local authority did not any longer contribute to pension funds. He would take upon himself the power of appointing the local committees. In future it would be made perfectly clear that the staffs of the local committees were State servants. Under Clause 2 the committees would retain all their powers under the Act of 1915 except with regard to the provision of medical treatment and employment. The committees having been relieved of all executive responsibility for the making of medical and other administrative arrangements, or for any expenditure under the warrants or regulations of the Ministry, would be able to devote their time to voluntary work and voluntary administration of pensions in their own locality. With regard to the question of interest, though not comparable with any statistical returns from the country as a whole:—

No. admitted to home.	Average stay.	Cases delivered.		Notified puerperal sepsis.		Ophthalmia neonatorum (number).	Maternal deaths.*	Fœtal deaths.†
		By midwives.	By doctors.	Number.	Deaths.			
9108	14 days.	6835	1844	28	10	74	57	583

* Including puerperal sepsis.
† Stillborn or within 10 days of birth.

Among 9108 women admitted, 28 cases of puerperal sepsis occurred and there were 57 maternal deaths, including 10 from puerperal infection. When ante-natal supervision is more fully developed it may confidently be hoped that the maternal mortality and the fœtal mortality will be considerably reduced. At the same time it must be remembered that a maternity home, like a maternity hospital, may be obliged to admit moribund patients for whom little can be done, and that more claims are made upon some homes than upon others to admit cases which should rather be sent to a hospital if such were available.

Conclusion.

The secret of the success of a maternity home does not lie only in convenient accommodation, modern equipment, and a competent staff. There must indeed be a conscientious application by the staff of the principles of aseptic midwifery, with no slurring over of details, and with accurate observation and recording of results. But this is not enough to satisfy a high standard. The mother coming into the home should experience a sense of calm relief, and should instinctively feel assured of a successful issue. Wisdom in the management of labour is essential; the mother must not be allowed to become fatigued or exhausted before the final trial of strength and control becomes necessary. The patient should only leave the home when well on the way to complete physiological restoration, feeling rested and refreshed. Breast-feeding should be regarded as a matter of course. Such an atmosphere is almost wholly personal, depending on all concerned in the management of the home, but most of all upon the matron and the inspiration she can give.

Properly directed and used, the maternity home will undoubtedly serve as one of the most effective weapons in the endeavour to raise the standard of midwifery and so reduce the disastrous death-rate among mothers. Rightly conceived, it forms one link in a chain. Standing alone, its activities are restricted, but in relation on the one hand with the ante- and post-natal clinic, and on the other with a maternity hospital (or medical school) and its consulting staff, in touch with the district midwifery of its own area and available for the local medical practitioner, its value as a treatment centre and as an example and incentive to sound midwifery practice can hardly be over-estimated. For well-managed midwifery secures something more than immediate safety; it serves as a means of encouragement to the whole instinct of maternity. Thus established and thus related a maternity home becomes an institution of the highest national importance, first, for the safe delivery of the child and the proper treatment of the mother, and secondly, for the advance of the science and art of medicine.

A GUEST HOUSE FOR MOTHERS AND BABIES.

A Guest House, available for breast-feeding mothers and their babies, the families of unemployed or disabled ex-Service men, was opened on July 13th by the Duchess of Albany. The institution has been organised and financed by the National League for Health, Maternity and Child Welfare, and the Save the Children Fund. It is called the Lady Forster Guest House for Mothers and Babies, and is situated in pleasant surroundings at Peak Hill Lodge, Sydenham, London, S.E. Only those mothers and babies are admitted who are not definitely ill, but would benefit by a change of air and good food. Guests must have attended an infant welfare centre at least twice before admission, and applications for admission must be made through the local medical officer of health or through a centre; a medical certificate must be submitted the day before admission. Guests pay their own fare to and from the home, but no charge will be made for their stay, which may extend up to four weeks. All applications for admission should be addressed to Miss Reed, Secretary, Babies' Homes Department, National League for Health, Maternity and Child W[illegible] and 5, Tavistock-square, London, W.C. 1, from [illegible] particulars can be obtained.

MEDICAL GOLFING SOCIETY.

At the annual general meeting, held on June 29th at the Florence Restaurant, Rupert-street, Dr. Rolf Creasy was elected President of the society, and Dr. Rolf Creasy, jun., 36, Weymouth-street, London, W., secretary and treasurer. The following constitute the committee: Mr. H. D. Gillies, Dr. J. Clarke, Dr. G. E. Haslip, Dr. M. J. Bulger, Mr. T. H. P. Kolesar, Dr. R. Cruise, Sir Milsom Rees, and Mr. Joscelyn Swan. It is proposed to hold an autumn meeting in addition to the usual summer one, for competition, at which Mr. Canny Ryall has presented a challenge cup. The President has also presented a cup, and Mr. Ernest Clarke will give a small cup each year to be kept by the winner.

NATIONAL COUNCIL OF PUBLIC MORALS.

A brief outline of the objects and work of the National Council has been published in the form of a 48-page booklet entitled "To Save the British Race." A preface is contributed by the Bishop of Birmingham, president of the Council, and the chapters deal with the action and reports of various commissions appointed by the Council to inquire into such problems as those of birth-rate, illegitimacy, and venereal disease. The chapter headed "The Health of the Race" contains statistics epitomising the returns of the medical boards of the Ministry of National Service in 1917-1918, and figures drawn from the medical inspection of public elementary schools, from National Health Insurance returns, and from the general death-rate for the country, together with a note on housing conditions and a suggestion for the inclusion in the Ministry of Health of a permanent anthropometric department, a vocational bureau, and an office of general registry of population. "Youth and the Race," "The Family and the Race," "An Imperial Race," and "The Amusements of the Race" are headings sufficiently indicative of the wide scope of the National Council's activities and the amount of information compressed into this useful booklet.

A MEDICAL MAN'S INVESTMENTS.

A medical practitioner recently brought an action against several defendants for the recovery of £375 which he had been induced to invest with them by representations of a misleading character as to the value of certain enterprises. These included interests in radium mines in Portugal, and processes for the production of an explosive, aniline dyes, and petrol from coal. The alleged fraud was denied by the defendants, who said that they had made their representations in good faith and that they were true. After a trial lasting three days a special jury found a verdict for the plaintiff, who to that extent is to be congratulated. In comment it may be observed that investments that will bring in large profits with any degree of security are very seldom offered to the public by the promoters of attractive speculations. It is they who expect to obtain the lion's share of the profits if any are forthcoming. A professional man will find the advice of his stockbroker or banker a valuable protection if he consults them. All this is so obvious that to write it appears unnecessary, until it is remembered that medical men and clergymen appear to be particularly gullible. Finance is outside their sphere of thinking.

County Borough of Halifax: Appointment of Medical Officer of Health.—In the advertisement of this appointment which appeared in our issue of July 9th, the salary was wrongly stated as £1000. The salary offered is £800 per annum.

Rubber sheetings and other productions treated by the "Mintite" patent finish, on which we commented last week, are obtainable from india-rubber manufacturers only and not from the owners of the patent.

THE LANCET: SUBSCRIPTION RATES.

Inland	One Year	£2	2	0

respectively, who were totally paralysed through wounds received in action, and who were so helpless as to necessitate their remaining in hospital; in how many of these cases the paralysis was permanent; and what was the number of ex-officers and men of the Navy, Army, and Air Force who were blind as a result of wounds received in action.—Major TRYON replied: There are 258 totally paralysed officers and men in hospital, but I am unable to say how many of them cannot be expected to recover. There are 1453 officers and men who are totally blind as the result of their war service. Of these 730 were blinded by wounds received in action.

Clinical Thermometers.

Mr. BALDWIN, President of the Board of Trade, introduced a Bill to regulate the sale of clinical thermometers. The Bill was read a first time.

TUESDAY, JULY 12TH.

Treatment of Bilharziasis.

Mr. GRATTAN DOYLE asked the Minister of Pensions whether, in view of his recently expressed sympathy with the proposed treatment of pre-recent war sufferers from bilharziasis by the Christopherson treatment, he would inform the House of the result of his communication with the Secretary of State for War on this subject.—Major TRYON replied that the necessary arrangements were being made to provide the modern treatment for men still suffering from bilharziasis contracted as a result of their service in former wars.

Conference on Treatment Bonuses.

Mr. ALFRED DAVIES asked the Minister of Pensions whether, on May 27th, 1921, a conference was held between the Ministries of Pensions, Health, and Labour on the question of the bonuses to be paid to men undergoing training during their treatment in sanatoriums; whether, having regard to his previous statements in respect of payment of such bonus, he would state whether the conference recommended any difference of procedure with regard to this matter; and whether he would say how many men who had undergone training arranged by the local insurance committee during a course of treatment had been paid the bonus prior to the date of the conference.—Major TRYON replied: One of several conferences on the matter referred to by my hon. friend took place on the date in question. The character of the training in individual sanatoriums which would satisfy the conditions necessary for the payment of bonus was discussed and agreed, and effect is now being given to the conclusions arrived at. I regret that the information asked for in the last part of the question is not available.

Ministry of Health and Sanatorium Treatment.

Mr. WALTER HALLS asked the Minister of Health whether he had refused to allow the Lancashire Insurance Committee of the National Health Insurance to assist the county council financially from their credit balances in providing and equipping a new sanatorium to make further provision for the treatment of insured persons and their dependants; and, if so, would he state the grounds for this refusal.—Sir ALFRED MOND replied: I presume the hon. Member is referring to the action taken by my department in connexion with the proposal of the Lancashire Insurance Committee for the application of the estimated surplus standing to the credit of the Sanatorium Benefit Fund of the Committee on April 30th last. The disposal of that surplus is governed by the provisions of the National Health Insurance (Termination of Sanatorium Benefit) Regulations, 1921, and I am unable to sanction any departure from those Regulations. Substantial grants are available from the Exchequer in aid of the provision made by the Lancashire County Council for the sanatorium treatment of tuberculosis.

Appointments.

BEGGS, S. T., M.D., D.P.H., has been appointed Medical Officer of Health for Middleton.

WALKER, H., M.B. Cantab., F.R.C.S. Eng., to be a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuits Nos. 2 and 15.

WARBURTON, G. B., Ch.M. Manch., F.R.C.S. Eng., Assistant Surgical Officer, Manchester Royal Infirmary.

Surgeons under the Factory and Workshop Acts: NEIGHBOUR, P. M., M.R.C.S., L.R.C.P. Lond. (Walton-on-Naze); BRUCE, R., M.D. Aberd. (Peterculter).

Vacancies.

Wigan Infirmary.—Jun. H.S. £200.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

The Chief Inspector of Factories announces the following vacant appointments.—Senny Bridge (Brecon); Swinton (Lancaster).

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Middleton-in-Teesdale.

Births, Marriages, and Deaths.

BIRTHS.

EDE.—On July 5th, at West Hill House, Calne, Wilts, the wife of Dr. Cuthbert Ede, of a daughter.

WELCH.—On July 3rd, at West Norwood, the wife of Dr. C. H. Welch, of a daughter.

WESTBY.—On June 27th, to J. T. Westby, M.B., B.Ch, and Marjorie Westby, L.R.C.P. & S.I. (neé McMullen) 9, Redcliffe Gardens, Southsea, a son.

MARRIAGES.

COLDWELL—SMITH.—On June 29th at St. James Church, Piccadilly, W., by the Rev. Prebendary Cronshaw, M.A., Walter Herbert Coldwell, M.B., B.S., to Barbara Joan Smith, younger daughter of Mr. and Mrs. A. E. Smith, The Quarry, Warwick.

MILLS—HAWES.—On June 29th, at St. Paul's Church, Portman-square, W., Dr. R. J. Mills, of Norwich, England, and Langenschwalbach, to Enid Ida Hawes, of Melton Constable, Norfolk. *American papers please copy.*

DEATHS.

BATSON.—On July 5th, at Marine-terrace, Rodwell, Weymouth, William Lascelles Batson, M.R.C.S., L.R.C.P., aged 69 years.

BLOMFIELD.—On July 8th, at The Drive, Sevenoaks, James Edward Blomfield, M.A., M.D. Oxon., aged 64 years.

RAY.—On July 8th, at Coventry House-chambers, Haymarket, after a long illness, Edward Reynolds Ray, M.R.C.S. Eng., L.S.A., aged 79 years.

SAVAGE.—On July 5th at his residence, 26, Devonshire-place, Sir G. H. Savage, M.D., F.R.C.P., aged 78.

the training of the practitioner. As a scientific profession we naturally aim at precision, but unfortunately take no steps to secure it in our daily work. Of what value, has any one ever asked himself, are the statistics upon which the computing officials of our Insurance Companies are accustomed to base certain actuarial statements which are accepted as guides to practice because they are founded upon statistics compiled from official returns which, we have reason to believe, are so hopelessly inaccurate that the results can at best be nothing more than rule of thumb guides? Some may possibly doubt this statement. Well, let anyone that does, institute an inquiry, say, into the accuracy of the death certificates as tested by post-mortem examinations in even the best of our clinical hospitals, and he will have his eyes opened, and his knowledge of practice may possibly lead him to draw a still more striking inference from the contemplation of the question of the accuracy of the returns throughout the country generally—outside the walls of our great hospitals.

Accuracy in diagnosis is, as I have said, of the first importance, but the search after truth in nearly every other direction as well is lax and indeterminate. Time will not permit me to pursue this most important subject, but I am convinced that until there is instituted in every large teaching hospital connected with our medical schools a statistical department with a highly trained official at its head—call him registrar, or what you will—whose duty it would be to collect and systematise all returns having accuracy as the constant aim, we shall continue to flounder on as we have been doing, groping after truth, and failing to read correctly the signs ready to hand and awaiting interpretation.

PRESENT WASTE OF RAW MATERIAL.

At present the returns are grossly inaccurate, and therefore many of the deductions are necessarily fallacious, whilst, for the want of a proper system, the waste of what I may call raw material is simply appalling. Observations of interest are made daily in the wards, post-mortem rooms, and the adjacent pathological and chemical laboratories of every teaching hospital of which use is never made, perhaps because they are isolated and their significance is not at the moment recognised. They are forgotten and, in many instances, pass even from the minds of the physician, surgeon, or pathologist who made them. Prof. Vincent tells us of a physicist who, long before the discovery of X rays by Röntgen, noticed cloudy markings upon his photographic plates whenever they were brought near to Crookes's tubes, but disregarded the observation as of no value. But instances could be indefinitely multiplied illustrative of the loss to science that may be involved in the failure to note, collect, collate, and investigate simple observations in medicine, surgery, pathology, and collateral sciences. This loss, which cannot be estimated, may very properly be compared with the loss to commerce and science involved in the crude uses to which tar was put before the discovery by Perkin of the colour mauve in the year 1856. Then followed other colours, together with benzine and its homologues, toluene, xylene, naphthalene, and anthracene, not to mention the manifold uses to which the long series of coal-tar derivatives have been put. So, without any great stretch of imagination, may we regard the waste of which I have spoken.

The fact is, the work in every hospital ward, post-mortem room, and scientific laboratory engaged in the investigation of disease for the purposes of teaching should be regarded in the light of research, and I think the assumption is only reasonable that the establishment of whole-time professorships in medicine, surgery, and midwifery in connexion with all our medical schools, together with properly organised registration departments, would help very greatly to promote this most important side of the teacher's fun[illegible] The importance of collecting this raw [illegible] present running to waste, will be recog- [illegible]ll, but especially by teachers themselves, who would have the results of their own labours, of their hospital's records and statistics by which to drive home the lessons they would inculcate, for, as Prof. Vincent very properly points out, students pay more attention to the personal observations of their teachers than to text-book statements. And further, research workers would be in possession of vast quantities of accurately noted and properly collated facts for the pursuance of their investigations. Thus our teaching facilities would be promoted, and our methods of instruction put upon a more satisfactory basis, whilst our knowledge would increase more rapidly and our science correspondingly benefit, and, transcending all, truth would be recognised as the presiding genius of our activities—our great purpose, our highest aspiration.

PROFESSIONAL EDUCATION A CONTINUOUS PROCESS.

The history of the general practitioner, the cornerstone of the profession of medicine, told in terms of his professional education, is, or should be, a record of continuous progress from the first stage of the introduction to the end of the last chapter, when finis marks his retirement or his decease. He travels along a road, at times rough and uphill, in which there is no break, and perhaps the easiest going, from the education point of view, is the outset, carefully indicated by notices bearing the official imprint of the curriculum. It is greatly to his advantage if, at the end of this part of his journey, he can secure a resident appointment in a first-class hospital. This cannot be too strongly emphasised, and it is impossible to over-estimate the value of six months' intensive training at this period of professional life, when responsibility and a certain measure of authority under discipline, with ample opportunity for the study of special problems, unite to shape and develop character, and furnish illustrations in abundance of the principles already forming the foundation of that superstructure of experience, the endowment of the trusted practitioner.

So helpful is this experience that the young graduate who has enjoyed it begins life with a take-off vastly superior to his neighbour who has not—who is, indeed, in comparison badly handicapped in the race of life. I feel so strongly upon this point—the advantage of a resident appointment—that I would like to take this opportunity to warn the rising generation against the practice, which is becoming only too common, of declining these appointments in order that an immediate financial return may be secured. It is true there are not at present hospital appointments for all, but sooner or later, with perhaps some adjustment of the period to be served, this want will be remedied, and I venture to hope that the time will come when a resident appointment will be found to be an essential feature of the training of the doctor. Having regard to its educational value, the period of the student's career at which the appointment is held is, I believe, a matter of great importance. During the war, when every available practitioner was called upon to serve, our hospitals had to fall back upon students to fill the posts usually held by qualified doctors, and it was the common experience that in the case of many students who were appointed before they had reached a certain stage in their professional training to fill these gaps the appointment and all that it entailed was not only valueless but actually harmful. But coming in due course at the end of the curriculum, and after the final examination, the experience is most useful, and cannot fail to produce a lasting impression upon the future career.

QUALITIES NEEDED FOR SUCCESS IN PRACTICE.

Whilst urging thus strongly the importance of post-graduate training I must not overlook the claims of the student to whose work, training, and examinations I may be permitted to make brief reference. I have already hinted that of the many who elect to study medicine there are some who are quite unsuitable, and who would be well advised to try some other walk in life. This I admit raises a very difficult question, and it is one to which hitherto vaginal examination with imperfectly cleansed fingers is fraught with danger, every forceps delivery is a potential source of sepsis either because the forceps are not used under aseptic conditions, or because lacerations may be caused which allow the entry of infection. Thus in 1920, 3942 women died and a much larger number were injured, many of them permanently, from causes which are almost entirely avoidable. It is a matter of common knowledge that a large proportion of the patients in gynæcological out-patient departments seek advice because of the effects of bad midwifery, and that much of the chronic ill-health from which so many working-class mothers suffer may be traced to the same cause. Such facts are a grave commentary upon the standard of midwifery practice in this country. The majority of those women might have been saved suffering and even death if the needful facilities had been available for their treatment and if practitioners of midwifery were better instructed and more alive to their responsibilities.

The Ministry of Health are anxious to do all that is possible to encourage effort to combat this regrettable and unnecessary loss of life and health. Action may be directed —first, (*a*) towards improving the midwifery service in the homes of the people by ensuring more skilled and careful professional attendance, and (*b*) by providing a supply of sterile equipment and appliances for those who cannot afford to pay for them. Secondly, it is also essential to increase the accommodation in maternity homes and hospitals so that all mothers requiring in-patient treatment may be able to obtain it and may be assured of safe and cleanly methods of delivery, while the obstetrician may be in a position to practise any operative measures which are needed unhampered by the difficulties inevitable in the private house. Thirdly, there is the need for a study of the physiology of normal pregnancy, labour, and lactation, our knowledge of which is far from complete, and this was one of the reasons for the establishment of such an institution as the Kaiserin Augusta Victoria-Haus in Berlin as long ago as 1909. A sufficient number of maternity beds, therefore, is one of the most important requirements of a complete midwifery service.

Until recent years almost the only accommodation besides the maternity hospitals in some of the large towns was to be found in Poor-law institutions and in private nursing homes. Maternity hospitals were unable to admit even all cases from their own districts, and many parts of the country were entirely unprovided.

Some Advantages of Small Homes.

After careful consideration the Ministry decided to encourage the establishment of maternity homes of, say, 10–20 beds, for normal and slightly abnormal cases rather than hospitals for larger numbers, fully equipped to deal with any complications. First, because of the initial expense involved; secondly, existing maternity hospitals already deal with many of the seriously abnormal cases; for the rest, a physiological rather than a pathological atmosphere should be the aim, and is more acceptable to the women. Further, it is desirable that maternity beds shall be accessible from the homes of the women they serve.[2]

General Requirements.

Maternity hospital construction is in a more or less experimental stage, but some general guidance being immediately necessary a Memorandum[3] was issued in January, 1920, dealing with construction, equipment, and organisation, an endeavour being made to simplify the design and eliminate redundance and extravagance while insisting upon the minimum requirements for safety. The Memorandum was concerned mainly with new buildings, but the recommendations were intended to apply as far as practicable to the alteration of existing houses.

The maternity home should contain wards for lying-in patients (some of which may suitably be one, two or three bed wards), one, or preferably two, labour-rooms, a prematernity ward, a duty-room, a receiving-room with bathroom, properly fitted sink-rooms, a nursery, a laundry, and separation or isolation-rooms, in addition to staff quarters. It should have an ample supply of hot water; there should be central heating and electric lighting; not less than 15–20 beds should be provided when possible, as smaller homes are more costly to maintain efficiently in proportion to the work done.

Patients are usually delivered by midwives, medical aid being called in as and when necessary. It is often convenient to arrange that several local medical practitioners shall be invited to deal with emergencies, but it is important that the clinical supervision of the home as a whole shall be vested in one medical officer, who will be responsible for the general standard of the midwifery practised and for the admission and discharge of patients. Whenever practicable a consultant medical officer should also be appointed. The matron should be a trained nurse as well as an experienced midwife, and even in a small home should have at least one fully trained assistant. It is difficult to lay down a precise rule as to the number of additional staff required, but there should not be less than one nurse or pupil for every three mothers and babies by day and for 8–10 mothers at night, in addition to labour room and special staff.

[Dr. Campbell then gave as examples of typical arrangements of well-organised maternity homes particulars of the Queen Mary's Maternity Home, Hampstead; St. Mary's Hostel, Croydon; Lewisham Municipal Maternity Home; and the Sunderland Maternity Home.]

Separate provision for antenatal care is unfortunately rare, though expectant mothers are sometimes admitted to the ordinary wards of a maternity home. A pre-maternity home was established in Liverpool in 1915 in connexion with the Maternity Hospital; the home contains 12 beds for pre- and post-natal care. It is in charge of a trained nurse-midwife and pupils from the hospital spend six weeks of their training there. The hospital is thus relieved of patients for whom it is not primarily intended, and the pupils gain much valuable experience of ante-natal hygiene.

As a rule patients suffering from venereal disease cannot be admitted to maternity homes because of the difficulty of effective separation. In some cases, however, special provision has been arranged. For example, in the Sunderland Maternity Home, already mentioned, in the Endsleigh Street Maternity Home, London (*five beds and a labour ward*), and in the Municipal Maternity Home recently opened in Battersea (*five beds and a labour ward*).

Limitations of Adapted Buildings.

It is relatively simple to plan a new building, but it has been found extremely difficult to adapt satisfactorily and cheaply the large mansion which is usually suggested as an ideal maternity home. The dangers of incompletely equipped maternity homes are frequently overlooked, and with every desire to make no unreasonable demands the Ministry have then the ungrateful task of criticising and apparently discouraging schemes which have been passed locally as satisfactory.[4]

One of the chief difficulties is to secure separation accommodation for cases of puerperal sepsis. There should be at least one single room reserved for cases suspected of infection. Although one can insist on an infected woman being removed from a maternity home for the sake of the remaining patients, it is no easy matter to find a place to send her where she will be skilfully treated. The alternatives are usually the workhouse or a fever hospital, neither of which is satisfactory for the reception of a patient dangerously ill and needing advice and treatment by an obstetrician. In view of the high mortality from puerperal infection this is a matter which demands the early and careful consideration of local authorities. The following suggestion offers a satisfactory solution in one case. It is proposed that a small ward in the local fever hospital shall be set aside for septic cases from the neighbouring maternity home and the district round, but that the maternity home and not the fever hospital shall be responsible for the nursing and treatment of all patients admitted.

Results.

In order to check the results obtained in maternity homes, the Ministry require immediate notification of all maternal deaths which occur, and an annual return showing the results of the work as a whole. The following table summarises returns made by 50 unselected homes for the year 1920 under certain headings, and the figures are of

---

[2] The arrangements proposed in Wiltshire may be quoted as illustrating a scheme for providing maternity beds in a rural county where in-patient accommodation is needed for women suffering from the ordinary emergencies of pregnancy and labour, and also for patients living in remote districts where neither doctor nor midwife can be obtained. It is suggested that there shall be five small centres rather than one home for the whole county, three to six beds being subsidised in existing homes or hospitals at Salisbury, Malmesbury, Swindon, Corsham, and Calne. The fact that the beds are associated with other hospital or maternity provision meets the usual objections to the independent two or three bed maternity home which is so difficult to supervise properly and economically.

[3] Memorandum in regard to Maternity Homes and Hospitals, with plans. M.C.W.15.

[4] To take some examples of this: A home was provided containing one ward large enough for three beds and one bedroom for the midwife in charge. There was no labour-room, no sanitary convenience, except in the yard, there was a movable bath in the ward from which water ran off by means of a drain in the floor, there was no means of sterilising dressings, &c. or of separating patients. In another case, besides insufficient staff accommodation, there was no reception-room, no duty-room, no sink-room or hospital sluice, no nursery, no milk larder, no sterilising plant and no separation-room, while the labour-room was small and had no special equipment. The importance of maintaining surgical cleanliness in the labour-room is not always understood. In one home, for instance, the labour-room had papered walls and rugs on the floor; in another, the only hospital sluice was fitted there; in a third it was proposed to utilise it also as an operating theatre for the removal of tonsils and adenoids from school children.

Lumleian Lectures
ON
SOME POINTS IN THE ÆTIOLOGY OF SKIN DISEASES.

Delivered before the Royal College of Physicians of London on March 10th, 15th, and 17th, 1921,

BY ARTHUR WHITFIELD, M.D., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE, SKIN DEPARTMENT, KING'S COLLEGE HOSPITAL.

LECTURE III.*

FOCAL INFECTION.

I NOW turn to what I believe to be one of the most important doctrines of modern medicine—namely, the causation of various symptoms by the absorption of toxin from one or more infected—areas in short, what is known as "focal infection." As in other medical matters, the skin offers a valuable field for the investigation of the correctness of this theory, and provides convincing instances of its correctness in some cases.

INFECTION FROM FOCI IN THE SKIN ITSELF.

A great deal of attention has been paid to the influence of infective foci on the skin, and in most cases the focus has been sought for, and in many located, in some organ other than the skin. As far as my reading has informed me, I think perhaps the fact that the original focus may be in the skin itself has received less attention than it merits.

As an example of what I mean I may instance ordinary pediculosis capitis. As a result of the invasion of the scalp by pediculi it is of course frequently the case that an attack of impetigo contagiosa develops as a secondary infection. In most cases nothing more occurs, but in a certain proportion a further train of symptoms may be observed.

The first sign to be added to those of the simple impetiginous lesion is the eruption of extremely fine miliary papules situated at the orifices of the hair follicles of the sides and back of the neck extending down nearly to the clavicles. These papules appear to be produced by the erection of the hair follicles and are at first only slightly if at all reddened. They may remain in this stage until they subside or they may redden and even become covered with minute vesicles, though this is uncommon. They resemble closely, except as to situation, the papules of lichen scrofulosorum. In some cases the secondary eruption is limited to this, but in others there occurs, after a variable number of days, an acute outbreak all over the chest, abdomen, and shoulders of an annular or figurate erythematous eruption with secondary scaling, such as would be classed in the ordinary way as a circinate seborrhœic eczema of the trunk.

If the pediculosis and impetigo of the scalp be efficiently treated and the trunk left alone, the whole of the eruption disappears speedily. In such cases I think the generalised eruption may be fairly assumed to be due to the absorption of toxin from the streptococcal infection of the scalp. A similar train of symptoms may develop in scabies, and frequently does so, but owing to the widespread diffusion of the primary disease, the separation of the primary and secondary eruption is much more difficult and less convincing.

I remember many years ago being fairly trapped by the secondary toxic eruption in two cases. This occurred when the seborrhœic eczema of Unna was in the height of fashion, and many of us were on the look-out for instances of definite contagion.

Two brothers attended my out-patient department showing very fine examples of "seborrhœic eczema" on the trunk and limbs. The history was that one had first developed it on the chest and then the second had begun to come out in a similar eruption a fortnight later. Being somewhat under the influence of the parasitic-contagious theory of seborrhœic eczema, I regarded these cases as good examples of its contagious nature. Later in the same afternoon I saw a girl suffering from ordinary typical scabies without any secondary eruption of note. She volunteered the fact that I had just seen her two brothers, and as they had not left the hospital I fetched them back and was somewhat crestfallen to find that their contagious disease was common itch!

It is also not uncommon to see in patients with a patch of so-called varicose eczema, i.e., pyogenic dermatitis, on the leg, the development of an acute outbreak on the arms and trunk of a papulo-vesicular eczema which will readily disappear if the original patch be brought under control. I regard all these as instances of intoxication from focal infection, but I confess that I am not certain as to how far they may be due to bacterial poisoning and how far to the absorption of the patient's own tissue products, to which I have already referred in the cases of extensive ecchymosis. Unfortunately, with the methods of investigation at present in our hands, I see no way of separating these two factors.

In this connexion I may draw attention to a recent paper by Prof. Bruno Bloch[19] of Zurich, who has for many years been studying the constitutional effects of trichophytic invasion of the skin. Prof. Bloch points out that this effect varies with the depth of the inflammation caused by the fungus. The ectothrix class is that which gives rise to the greatest degree of constitutional disturbance; the actual toxin present is not specific for one variety of fungus, but is common to all the trichophytons, the microsporons and the favus fungi, the achorions. He therefore proposes for this common toxin the name of "mycine." Resulting from the absorption of this toxin, either naturally in the course of the disease, or from an experimental and therapeutic injection of vaccine prepared from cultures of the fungi, he and others have observed eruptions on distant parts of the body. A number of observations by different investigators now exist in which the appearance has been noted of an eruption closely resembling that of lichen scrofulosorum. Cases have also been observed in which the eruption has been squamous in character, resembling that of "seborrhœic eczema."

It is interesting to compare this with what I have just described in connexion with streptococcic impetigo. Also, seven cases in all have been collected by different observers in which apparent characteristic erythema nodosum has appeared as the result of deep trichophytic infection, and, lastly, scarlatiniform erythema and erythema exsudativum multiforme have been seen.

The type of eczematous eruption which is, in my opinion, most typically the result of focal infection is that which I term for convenience "flexural eczema." In this case the eruption has its main seats in the axillæ, the groins, the umbilicus, the submammary regions in women, the flexures of the knees and elbows, and the base of the neck. In most of my cases the focus has not been situated in the skin itself, but it may be.

A middle-aged lady consulted me for a widespread and severe eczematous eruption with the above distribution. On inquiry I found that she had scratched her neck with a pin or the metal support of a collar, and the small wound had festered, and about ten days later the generalised eruption broke out and deprived her of rest at night. The whole of the eruption yielded at once when the original pyogenic patch was efficiently treated, and for the subsequent several months during which I heard of her showed no tendency to recur.

As I have already said, I do not find that the focus of infection is nearly always in the skin itself. On the contrary, I think it is more often elsewhere. The gums, teeth, tonsils, and accessory sinuses of the nose are frequent offenders, less frequently in my experience the uterus, bladder, and urethra.

ORAL SEPSIS.

Dealing first with the gums and teeth, I have notes of very many cases of the most diverse eruptions which I consider to be proved to be due to chronic

LIBRA

An Address
ON
ACCURACY IN DIAGNOSIS.

Being the concluding part of the Presidential Address at the Annual Meeting of the British Medical Association delivered on July 20th, 1921,

BY DAVID DRUMMOND, C.B.E., M.A.,
M.D. DUB., D.C.L. DURH.,
VICE-CHANCELLOR AND PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY OF DURHAM; PRESIDENT OF THE COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

REVIEWING forty busy years of consulting practice Prof. Drummond set himself to answer the question: Are we satisfied with things as they are, and, if not, in what manner can they be improved? The first part of his address dealt critically with the position now occupied by the medical profession in the scheme of national polity. Prof. Drummond then turned to the room for improvement in the quality of service given.

In thus suggesting that there is room for improvement in our service, we must remember we are dealing with knowledge in the practice of medicine and surgery, which it is the aim of all workers, in the interests of all, to raise to the highest possible level of exactness. This is a design to which every practitioner could under favourable circumstances contribute, though at present he is heavily handicapped, as he has to live and work in the most depressing atmosphere of constant doubt—of problems unanswered, of opportunities lost. This wail, for it is a wail, will probably suggest to the minds of all here one of the chief difficulties in the way of progress, and will, I hope, elicit a sympathetic interest in the problem—How are these difficulties to be overcome?

POST-MORTEM VERIFICATION.

It may perhaps be a surprise to many, but not, I suspect, to the more thoughtful section of the public, that the diagnosis in many cases (very many, I am afraid) is only a matter of opinion, which must remain in doubt unless cleared up by an autopsy, and in making this statement it will not, I trust, be thought that I am casting blame upon the doctor; far from it, for the marvel is that his opinion is so often correct, considering the difficulties with which his path is beset in his endeavour to contribute his quota to the common cause. I have alluded to this state of matters as an atmosphere of doubt; it is more so, it is in the highest degree discouraging and is calculated to kill the scientific spirit with which it is our aim at college to inspire all our students; and in claiming the right of the doctor to follow up the lines of his training, I am urging a change in the interests of all; in the interests of scientific medicine and surgery, and particularly in the interests of his patients.

I found myself recently discussing the present status of the medical practitioner with a prominent member of our profession, a man of high standing and wide experience as a general practitioner, and the conversation inclined towards the question of education and training of the doctor, and I asked him what in his opinion could be done to improve his scientific and professional standing. His reply was definite and uncompromising. "The one thing above all others," he said, "calculated to elevate and generally to improve the standing of the general practitioner is opportunity for post-mortem verification or the contrary of his expressed opinion." He added, "We shall never be any better until we are entitled to claim, with the knowledge that we shall not be denied, a post-mortem examination." I was much impressed by this view of the matter, coming as it did from one whose knowledge and experience of general practice could not fail to make clear to him the revolutionary character of the suggestion, and how inconvenient it might be to have to acknowledge our mistakes, for, indeed, the opinion my friend expressed coincided fully with my own. Revolutionary it certainly would be; but what an enormous gain to have our doubts set at rest; and it is not too much to hope that before very long both the public and the profession will be educated up to feel that truth above all things must prevail. Could we but engender amongst our members the love of truth as the fundamental essence of our professional life and the mainspring of our activities, and could we also inspire eagerness to search after and courage to proclaim it, what a noble profession would be ours! I believe the desire to rise and live up to our loftiest professional aims is there; but we are unfortunately trammelled and moulded by public opinion and prejudice and the requirements imposed upon us by the State. The very loftiness of the estimate which is entertained of the doctor is his undoing, for he is set tasks which he cannot perform; he is expected to make bricks without straw, and not infrequently we assume to ourselves personally the public estimation of our calling, though this I believe in the main to be a failing of youth.

ITS PLACE IN POST-GRADUATE TRAINING.

In urging the importance, nay more, the necessity for greater facilities for post-mortem investigation in clearing up doubts which must arise in the mind of the doctor in many cases, I am indicating the most important step towards a rational scheme of post-graduate training. It is, perhaps, unnecessary to insist upon the enormous advantage it would be were post-mortem examinations universal, for all, save those who never make them, are prepared to admit their educational value, and I have little doubt that the opposition to a movement in this direction, begotten of prejudice in the public mind, would soon vanish were the incalculable service to the science of medicine made sufficiently clear. I have said that medicine has advanced in every direction, but I regret to have to admit that the advance along certain diagnostic paths is not as rapid as we could wish, and not nearly so rapid as it would be were post-mortem examinations more frequent; and I believe I am stating what is correct when I say that in private practice they are not even so frequent as they were in my earlier days. It is true that in a few of our large hospitals throughout the country, in the wards of which students of medicine enjoy the inestimable privilege of clinical study, the enlightened committee of management now sanctions an autopsy in every case under fitting limitations, but in the majority of our clinical hospitals the old restrictions still obtain and the study of pathology is still hampered as of old to the great disadvantage of the medical school and, if they but knew, to the public themselves.

Did anyone question the service rendered diagnosis by the substitution of the unclouded prospect of certainty for the befogged atmosphere of uncertainty—the educational value of exact diagnosis in a doubtful case—let him ask himself what he has learnt from the modern surgeon's exploratory operations, and he will candidly admit that nearly all he knows of abdominal diagnosis is the outcome of the lessons he has learnt in consequence of the ease and impunity with which we can now "open and see." It is the examination *ante* which is often effectual in averting the *post*.

We all recognise the value of post-graduate teaching in connexion with the Fellowship of Medicine and Post-Graduate Association, and similar courses of study instituted in various centres, and no doubt many take advantage of these opportunities, but after all they are only supplementary to the curriculum of the student and cannot take the place of the natural progress and ever-ripening experience, the outcome of facilities which I would like every practitioner to be able to claim as a right, and for which I have little doubt sooner or later the State will make provision in the interests of medical science and the health of the nation.

ACCURATE DIAGNOSIS IN DAILY WORK.

The importance of accuracy in diagnosis cannot be overstated, and it is unnecessary to insist upon the value of the autopsy in promoting it as well as in disease to be attributed to disease of the tonsils appears to me due to the absence of any very definite clinical appearance of the tonsils in some cases.

To the recent publication by Dr. Barber on the association of infection of the tonsil with alopecia areata, Mr. Zamora has appended a short article on the signs of tonsillar infection. I confess that this article left me with a sense of depression, as it seemed to me that almost the only certain way of diagnosing tonsillar infection was to enucleate the organ and examine the deeper parts bacteriologically. Nevertheless, short of this there are, of course, many cases in which examination carried out with a high degree of skill will reveal perfectly certain disease.

The types of disease that I have chiefly seen associated with tonsillar infection are lupus erythematosus and "flexural eczema." In carrying out my investigations I have differed slightly from Dr. Barber, who has, I think, generally had a streptococcic vaccine prepared from the tonsil and used it at once. I have preferred, after the enucleation of the tonsil and the preparation of the vaccine, to wait and observe the change that takes place from the mere abolition of the infective focus before using the vaccine. I have done this in order to avoid being misled by the improvement which follows in so many diseases after the injection of a non-specific vaccine, and is termed "protein shock."

My experience has led me to be confident of the direct effect of infected tonsils, with or without adenoids, in the production of certain cases of eczema and lupus erythematosus.

A child aged two was brought to me with a severe eczema of the "flexural" type. The family history was about as bad as it could be, asthma and eczema occurring very frequently on one side and eczema on the other. The child herself was liable to an irritable cough and was suspected of being in the early stages of asthma. The eczema came on in severe attacks, but did not clear up entirely in the periods of quiescence. The highly intelligent nurse told me in the course of my examination that the attacks of eczema were invariably preceded by a period of four or five days during which the child snored loudly at night and had difficulty in breathing during the day. On examination of the throat it was found that the tonsils met in the middle and appeared to be as large as walnuts. I advised enucleation and this was done in my presence, a large patch of adenoids being removed at the same time. I secured a culture of streptococcus pyogenes from the depth of the tonsils and prepared a vaccine in case of need, though as a matter of fact it was never used. The only local treatment given was lotio nigra, yet the eczema all disappeared within a few weeks, and the cough and difficulty of breathing ceased. Two years later I heard that she was still well, though her skin remained a little more sensitive to climatic variations than that of most children.

Before the operation this child had had very expert local treatment, and a course of inoculations with organisms cultivated from the skin. No benefit had resulted from these forms of treatment, and scarcely any local measures were necessary after the pharynx was cleared. It will be noted that the patient was very young, and the disease had consequently not been running for a very long time. I believe this to be important, and that if the patient is left with the focus until adult life cure will be problematical, though improvement seems almost always to occur.

I have now under observation from time to time a girl of about 20 who has suffered for very many years from an eruption which is, I think, identical with what the French call "prurigo à papules grosses." The eruption comes up as lenticular papules, almost entirely confined to the arms and legs, most profuse on the forearms and below the knees. These papules are maddeningly irritable, and she only obtains relief by decapitating them with her nails. The skin of the affected region is, in consequence, somewhat pitted and very harsh. When she consulted me I advised that her large and very foul tonsils should be removed, more especially as there was a history of repeated tonsillitis. This was done in King's College Hospital, and she had two years of complete immunity from her trouble. She then came again with a milder attack of the same thing. I found on inquiry that she had had several infected teeth removed and the relapse occurred soon afterwards. I hazarded the guess that if the mouth were put into thorough order the rela[illegible] die away again, and this has occurred almost [illegible] any little illness such as a severe cold or gastric upset will cause a slight and temporary return of the old trouble. My idea is that the many years of intoxication of the skin have so weakened its resistance that it will be only after a very long time, if at all, that it can return completely to the normal.

As regards the connexion of lupus erythematosus with infected tonsils, the following appears to me to be a convincing case.

A girl aged 17 was brought to me for several patches of lupus erythematosus of the congestive type, with some scaling and atrophy. There was present in addition to the lupus erythematosus some septic dermatitis of the nares. The history showed that her father had died of tuberculosis of the lungs and larynx, a fact that caused me to be very suspicious that the girl herself might be suffering from latent tuberculosis. The tonsils had been guillotined, but not enucleated, in childhood, and showed to my eye nothing abnormal. The dermatitis of the nares led me to suspect trouble within the nose, and she was therefore taken to a first-class rhinologist, who reported nothing wrong within the nose or in the pharynx. She was then thoroughly examined by an expert physician with a view to finding or excluding tubercle. He reported that she was free from evidence of active tubercle, but said that there was pus in one tonsil. The tonsils were accordingly enucleated, nearly a drachm of pus being found in one of them, and from this pus a vaccine of streptococcus pyogenes was made, though never used. In two months' time the lupus erythematosus had disappeared, and she remained clear for nine months. At the end of this time she contracted measles, and a little while after this a mild return of the eruption occurred, which I am hoping will disappear spontaneously.

The influence of acute specific fevers on lupus erythematosus is familiar to me, and I remember well one man who had so slight a lesion on his nose that I could only make a tentative diagnosis. I was taken, however, later to see this patient while suffering from enteric fever, and found that the effect of this was to bring out a widespread attack of lupus erythematosus over the nose, both cheeks, and ears. This subsided after his convalescence from the enteric fever.

This effect of acute illnesses on lupus erythematosus is, I think, also interesting because it is the converse of what is generally observed in eczema and sometimes in psoriasis. Certainly, in the former an acute febrile illness is generally accompanied by an amelioration in, if not the disappearance of, the eczema. So much so is this the case that it is well known to the lay public, and they carry it further and state that while they have the eczema they do not suffer from other troubles, and when their eczema is in abeyance joint pains and general malaise occur.

As to the right position of cause and effect in this I do not wish to be dogmatic, but from careful observation I am inclined to think in most instances the illness is the cause of the fading of the eruption and that the fading of the eruption is not the cause of the illness. Others, among whom may be mentioned Dr. Brocq of Paris, hold the opposite view, and consider it dangerous in some cases to cure a widespread eczema too rapidly.

With regard to this view I am in complete agreement with Sir Malcolm Morris in finding myself unable "to calm down abruptly" cases of furious eczema. In fact it is only in those instances where I have been able to detect more or less accurately the causal agency and to remove it that any of my cases of severe eczema have got well abruptly.

NEUROSIS AND SKIN DISEASE.

The last ætiological factor to which I shall allude is the influence of the nervous system on skin diseases. This is a matter of such intense difficulty that I approach it with considerable misgiving. I think there is no doubt that in many instances the prejudices of the observer have led to the drawing of unjustifiable conclusions, and that slipshod clinical examination has resulted in the attributing of eruptions to the nervous system when they are plainly due to another cause. On more than one occasion I have seen that much mistaken disease, scabies, attributed to nervous shock.

The frequently mistaken attribution of skin disease to obscure defects of the brain summed up a attention has been given, nor can it very well be discussed in a public address. I pass it by, therefore, with the observation that it is a question that deserves our attention, and I would particularly commend to the authorities the question of preliminary general education of the doctor.

Success in the profession of medicine, by which I mean the proper fulfilment of the duties of the practitioner, is attained by the exercise of certain faculties which are capable of development. Among these gifts stands out prominently the faculty of taking notice. This gift—the power to observe—is in many people, until developed by special training, entirely in suspension, but there is no endowment of which the complex mental organisation of man is composed more capable of development than this. A party of grouse shooters, when tramping through the heather between the rows of butts, made a search for white heather, and the host was the only member of the party who succeeded in gathering the white sprigs. He was invited to explain his success. "Oh," he remarked, "you know I am a manufacturer, and I have trained myself to observe flaws in certain goods when passing rapidly through the galleries." And in like manner, I maintain, may the faculty be trained in the case of the students. The training could go on *pari passu* with the teaching of physics, chemistry, anatomy, and physiology, in connexion with which courses the habit of observing accurately might be acquired, to be further developed in the out-patient department, wards, and post-mortem room. The opportunity to promote this kind of training will increase in the case of anatomy and physiology when these subjects are brought into closer touch with clinical work, as recommended by Keith, Berry, Vincent, Lewis, and others, the importance of whose suggestions, it is to be hoped, will be recognised and put into universal practice. These have for their aim the realisation of the vision of the prophet Ezekiel—to make the dry bones to live; the giving of a vital interest to subjects at present dead, at least in the mind of the average student; the bringing into prominence from the outset their practical utility, and thereby furnishing a living continuity between the earlier and the later subjects of the curriculum.

DIAGNOSIS OF EARLY DISEASE.

The question of special instruction of our students in the diagnosis of early disease is intimately associated with this subject. It is recognised by all that the earlier a diagnosis is made the better for the patient, and notwithstanding this self-evident truth it is remarkable how little attention has been given to the training of students in the recognition of the earliest indications of disease. The wards are, as a rule, filled with examples of advanced disease, and the subjects selected for clinical lectures and demonstrations are usually conditions in which history and physical signs are as far as possible characteristic and strongly marked. And, of course, this is almost inevitable, for the student has but a short two years into which to crowd his clinical training, and he is naturally attracted by outstanding and obvious pathological changes in which the signs and symptoms are more or less gross and appeal to his untrained senses. It is evident that something must be done to help forward the student's training in this direction. At present, as things are, his opportunities are derived from attendance in the out-patient department of the hospital, where as a rule a large number of patients have to be seen, and the teacher is a member of the junior staff, and is not infrequently only just qualified. I have no wish to under-estimate the value of the out-patient teaching, but the diagnosis of incipient disease is at once the most difficult and the most important problem the doctor has to face, and yet it must be admitted that hitherto but little attention has been given to this phase of clinical medicine. It is generally supposed that the art of early diagnosis will be acquired later in the course of practice, but it is then too late, for in panel practice there is, I fear, contrary to the expectations of the authors of the present system, no such thing as early diagnosis. The truth is there is no time to work out an accurate diagnosis in an early case in a crowded consulting room in panel practice, and there is a danger of the aptitude becoming a lost art. For, on the one hand, the doctor has not the necessary time to devote to a careful examination, and, on the other, the tendency of the present day is to ignore physical signs and to rely altogether upon laboratory methods. I would, therefore, earnestly plead for some alteration in our system that will give due prominence to training in the methods of early diagnosis.

It is obvious that a thoroughly serviceable knowledge of the functions and structure of the human body in health and the possession of well-trained senses—the ability to observe—are essential to successful diagnosis. Nevertheless, I believe I am correct when I state that comparatively few practitioners are familiar with the range of the limits of health as signified by signs evident to the trained senses. For instance, to take but one example, failure to recognise the fact that our stethoscopes employed in the examination of chests (heart and lungs) detect the widest possible differences in normal individuals has been the source of much error in practice. The truth of this assertion was made apparent in connexion with recruiting examinations during the war, when thousands of perfectly healthy young men were graded low, or rejected altogether, on account of the erroneous interpretation of some physical sign. And, in the same way, everyday life assurance problems are settled incorrectly on similar grounds. The fact is, when we recognise that a comprehensive knowledge of the functions of man, together with the indications of their working, is necessary to enable us to detect abnormalities, it is plain that the normal state demands our very special attention, for we are dealing with what is at once the most perfect and the most faulty machine of creation.

THE WORKING OF THE HUMAN MACHINE.

Students in future will be taught the working of this machine in such a way as will make it more easy for them to appraise at their proper value departures from the normal; and it will be the aim of the teacher to render his teaching more vivid and to demonstrate as far as possible its bearing upon clinical problems.

I am fully aware that there are objections to this attempt to abolish the line of demarcation between pure science and practical application, and that from a university point of view, on the ground that the foundations of applied science are ever extending, it would be a mistake to do anything that would tend to limit the range of the student's studies; but the patient must be our first consideration, and it cannot be denied that the practical side of the curriculum is hazardously short.

I must not conclude this dream of progress without a reference to the examination test which all students of medicine must pass before their names are inscribed upon the Official Register. For long I have questioned the wisdom of the present system, which wholly neglects to take into account the candidate's record as a student. He is known as a number, his anonymity is preserved as far as possible throughout the examination, and no notice is taken of the results of class, prize, or scholarship examinations, or of what should be the most valuable evidence of teachers of industry and capacity during his period of training; indeed, as far as I know, except in the case of one or two universities, there is no official record kept. The examination is not competitive, and the object of the examining board, composed of home or internal and external examiners, is to impose a test that will safeguard the public. But as such a test it is necessarily very imperfect, since it takes cognizance only of the present, ignores the past, and makes no attempt to anticipate the future. I welcome, therefore, the support and recommendation of the General Medical Council in this direction.

I repeated the procedure with improvement. It is not clear in what way the beneficial effect is produced since, as already stated, there does not seem to be any notable abnormality present either in the pressure or quality of the fluid, but it would seem to indicate some obscure relationship between lichen planus and the central nervous system.

These are the chief diseases that I have observed in relationship to the psychical state of the nervous system, and in the case of lichen planus there seems to be some relationship to the organic side although it is obscure. There are, of course, many other diseases, such as glossy skin, herpes zoster, and probably erythromelalgia which are connected with inflammatory disease of the peripheral nerves and ganglia. With these I do not propose to deal. There is, however, another group to which I should like shortly to refer.

REFLEX IRRITATION.

In 1897 Dr. Pernet [25] published a case of relapsing herpes zoster of the right side, once on the body and three times on the neck and head. In this case he suggested ocular strain as a possible cause, and the oculist to whom he sent her found hypermetropic astigmatism. In 1903 Dr. Pernet referred to this case again and reported that she had remained free since the eyes had been corrected. It is noteworthy that in this report Dr. Pernet stated that he thought some cases of alopecia areata might turn out to be associated with eyestrain. In 1902, a year previous to Dr. Pernet's second communication, Jacquet [26] published a couple of long articles on alopecia areata, and claimed that a great number of cases in children were associated with dental irritation and were produced reflexly. Curiously enough he noted that enlarged tonsils and adenitis of the neck were also frequently met with, thereby anticipating Dr. Barber, though I think he implied that the tonsils acted rather by nerve irritation than as sources of septic intoxication.

This theory of reflex irritation set us all to work to make control observations. Most observers express great doubt as to the validity of the theory, but I myself, though uncertain, have thought that there was some evidence in its favour, as I have already stated in an earlier part of these lectures. In 1904 [27] I published a series of cases of alopecia areata associated very definitely with eyestrain and headache. My cases had been extremely resistant to treatment by well-known experts before they came to me. With the exception of the prescribing of glasses no treatment was given and the results were in all cases striking. At the time I thought I had hit on the cause of the disease, but I soon found out that these cases were quite uncommon. In only one case with this ætiology was the age below 20, and in nearly all the patients were in the neighbourhood of 40. In every case where the relationship was apparently established by the resulting cure on correction of the error of refraction, headache was a marked symptom. Since that time I have seen a fair number of cases in which I think that the wearing of glasses and the rapid recovery of the hair has offered good evidence of this relationship, but as I have said it is certainly not the commonest cause, and I am not certain that it accounts for any of the juvenile cases—i.e., those between 7 and 12.

I may conclude these remarks with an apology for the somewhat discursive and unsystematic treatment of my subject. Some points, however, there are that I have endeavoured to bring out in these lectures:—

First, that a careful examination of the clinical signs on the skin is a necessary prelude to the forming of a correct opinion as to the ætiology of the eruption, since without this wild theories will be substituted for real knowledge.

Secondly, that in some of the recent work our attention has been directed to a greater extent towards the working out of the whole physical condition of the patient, and dermatology has therefore been brought into a closer relationship with general medi

To these I may add a third—namely, that this deeper insight which we have begun to gain into the true ætiology of disease as it affects the skin has been already in many cases the means of securing a greater efficiency in the treatment of our patients.

Finally, I should like to thank those of my colleagues in the specialty who have afforded me a frank discussion of ætiological difficulties, and especially would I express my gratitude to Dr. G. A. Harrison, lecturer on biochemistry at King's College Hospital, for much valuable help.

A CASE OF
PRIMARY TUMOUR OF THE PLEURA.

BY E. H. EASTWOOD, M.B., CH.B. LIVERP.,
PATHOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;
AND
J. P. MARTIN, M.A., M.B., B.CH. BELF.,
LATE HOUSE PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

PRIMARY tumours of the pleura are interesting by reason of their rarity and difficulty of diagnosis. The case here described has been thought worth recording in that the evidence of its primary nature is clearer than in many recorded cases, the patient dying at a comparatively early stage, before metastases in other organs had formed.

History.

J. H. C., a well-developed, well-nourished man, was admitted to the Royal Southern Hospital under Dr. C. J. MacAlister on Jan. 29th, 1921. He gave his age as 38 years. He said that for about five weeks he had been feeling "out of sorts," had a slight cough, and suffered from shortness of breath; the breathlessness had gradually increased until he was unable to go about his work (publican), and was compelled to sit in a chair all day. He had no pain in any part of his body, but for a fortnight he had been aware of a tender spot on his breast bone.

On admission patient had a temperature of 98·4° F.; pulse 104 per minute, respiration 28 per minute; slightly cyanosed. Veins in neck dilated and prominent, but not pulsating. He had a slight cough, amounting to little more than "clearing his throat," and his voice was hoarse, but he said it had always been so. There was a prominence on the chest just below the angle of the sternum, and at the left side of this prominence, at the junction of the third costal cartilage with the sternum, there was a point of great tenderness. The surrounding area was not tender. The other signs were those of a large right-sided thoracic effusion—dulness on percussion over the whole of the right side of the chest and extending in front across to the left border of the sternum above the area of cardiac dullness; no Grocco's triangle; vocal fremitus absent on the right side; breath sounds absent anteriorly but present posteriorly, bronchial in type, and weak; vocal resonance much less on the right side than on the left. The apex beat was displaced outwards, being situated 2 inches outside the nipple line and in the sixth interspace; heart sounds normal. There was no other visible or palpable pulsation in the chest. Measurement showed that the two sides of the chest were equal. The lower border of the liver could be felt 2 inches below the right costal margin in the nipple line; the organ was of normal consistence, smooth, and not tender; the abdomen was otherwise normal. The pulse was small, soft, regular, and equal in the two wrists; the vessel wall was not palpable. The urine was normal—sp. gr. 1020 acid, no albumin or sugar. No enlarged glands were to be made out anywhere in the body. The pupils were equal and reacted to light and accommodation.

Progress.

As there were all the clinical signs of fluid in the right side of the chest and patient was in need of early relief, a infective periodontitis. In every case I have tried to survey the position critically before assuming the direct connexion. Oral sepsis is so common and the evil effects ascribed to it so multifarious that one naturally acquires a feeling of mistrust, especially since one so frequently sees terrible mouths associated with otherwise apparently faultless health. Also I have a vivid memory of one lady who was treated from June to October for what was obvious scabies by the inoculation of a vaccine made from her suspected gums.

The postulates that I have laid down for myself have therefore been the following: (1) that the skin disease shall be either chronic or frequently recurring; (2) that after a thorough examination no other cause shall be found; (3) that the usual methods of treatment shall be found unavailing; (4) that appropriate treatment of the teeth and gums shall be followed by cure or at least marked improvement.

The cases which have complied with these tests have belonged either to the group containing purpura, erythema multiforme, and lupus erythematosus, or have been forms of eczematous dermatitis. As regards the latter I believe Dr. Barber considers that a certain type of eczematous dermatitis of the arms showing large, chronic, and well-defined patches is characteristic of chronic infective periodontitis.

The first case in which my attention was drawn to the possible connexion between disease of the skin and that of the gums occurred in my practice 13 years ago.

This was the case of a lady who suffered from lupus erythematosus in small indolent patches on the face. She was under my care for the face, and under Mr. J. G. Turner for pyorrhœa. The patches yielded rather satisfactorily to local treatment, but fresh ones continually appeared. It was then noticed that fresh exacerbations invariably occurred about two days after local treatment had been applied to the teeth. Unfortunately I had no opportunity of observing the final result of the treatment of the teeth, as I lost sight of the patient.

Since then I have seen a fair number of such cases, and some at least have got well in a comparatively short time after wholesale extraction has been performed.

As regards the erythema multiforme group the following is a typical case.

A gentleman aged 70 years consulted me for a nodular erythema, somewhat resembling chilblains, on the hands. The duration of the eruption was two years, and although it had varied in severity the hands had never been clear during this period. After examining him carefully I found what I thought was pyorrhœa of several teeth, although he told me that his dentist had assured him that his mouth was clear. I ordered him quinine in high doses, and suggested that he should obtain a further dental opinion and if necessary submit to extraction of the unhealthy teeth. A month later I heard from him that the quinine had apparently caused the entire disappearance of the eruption in ten days, but that it had returned, was not further controlled by the quinine, and he was therefore going to take my advice about his teeth. I did not see him again, but was told by the dental surgeon whom he had consulted that many tooth sockets were heavily infected, and that after numerous extractions the erythema had entirely disappeared. I therefore wrote to the patient later on asking him whether he was in reality quite well, and whether he was confident that his recovery was entirely due to the dental treatment. I received a somewhat enthusiastic reply stating that he had entirely recovered, but that at first he had been somewhat depressed as the early result of treatment was to make his hands distinctly worse, and that an indurated lump had appeared in the muscle of the right shoulder. All these symptoms had, however, slowly disappeared, and at the time of writing he was quite clear and had been so for a considerable period.

Many years ago there was a considerable discussion as to the nature of the disease described by Bazin under the name of erythema induratum scrofulosorum. Bazin's description was applied to the nodes that occurred in the legs of young girls whose occupation involved prolonged standing. The nodes frequently softened and led to obstinate ulceration. The question of the ætiology of this form has been, I think, answered by inoculation experiments and tuberculin injections, and the disease has been proved to be tubercular in nature. Later on, however, I described some cases which occurred in middle-aged rather than young women, in patients who suffered from dyspepsia, "rheumatism," and varicose veins. I pointed out that the nodes in these cases were much more painful; that they seldom, if ever, produced ulcers; that they disappeared fairly quickly with rest in bed; that the patients gave no tuberculin reaction; that inoculation experiments gave negative results; and that the histology differed in some degree from that of the nodes in Bazin's disease. At the time I offered no theory as to their ætiology beyond attaching them to the group of the obscure "chronic rheumatic" type. Looking back on my cases, I remember that they all had bad teeth, and I incline to the view that these should be put into the group of infiltrative erythematous lesions due to focal infections.

An American author, E. D. Chipman[20] has claimed that lichen planus is often associated with and is probably caused by abscesses at the apices of the teeth, but this I have been unable to corroborate. I have seen a goodly number of cases of lichen planus in which careful radiographic examination has failed to reveal any evidence of disease of the sockets, and also I have seen cases in which the eruption has appeared in patients who have been completely edentulous for several years.

Recently Dr. Barber[21] has published a paper in which he urges the claims of alopecia areata to be due to focal sepsis, in some cases pyorrhœa, but more frequently septic tonsils. It is many years now since Jacquet announced his theory that this disease was due to decaying or erupting teeth, a theory difficult to confirm or combat, but one in favour of which I have seen some evidence. Jacquet's idea was, I think, to attribute the disease rather to nerve irritation than to bacterial intoxication, and the series of cases that I published in which alopecia areata of middle age, associated with headache, responded to correction of errors of refraction after resisting other treatment seems to fall into line with Jacquet's theory of nerve irritation.

DENTAL IRRITATION.

Before leaving this question of the teeth there is another group of cases to which I should like to refer, though I do not think these belong to the infective group. The first is the occurrence of a persistent erythematous patch on one cheek and found in children only. The eruption is not common, but I have now seen a considerable number of cases. There is no disturbance of the texture or consistency of the skin, but merely the presence of an ill-defined, circular patch varying in diameter from half an inch to an inch, and of a bright red colour. These patches have proved, in my experience, resistant to treatment, have lasted several months and eventually disappeared without leaving any trace. Most of the patients in whom I have seen the eruptions have been cutting their permanent teeth, and I am inclined to think that it is the canines and first molars that are most often associated with it. Another eruption, possibly allied to this but more acute, is the so-called herpes of the cheek, which is almost limited to children. Herpes febrilis of the lips, nose, and chin is, of course, commonly associated with colds, pneumonia, gastritis, and other acute disorders, but the peculiar discoid group of vesicles in the neighbourhood of the zygomatic process is, as far as my experience goes, limited to children during the second dentition, and I have seen these patches relapse just before the eruption of the permanent molars time after time.

TONSILLAR INFECTION.

The tonsils are naturally regarded by the believers in focal infection as a fruitful cause of skin eruptions. Dr. Barber, I believe, holds the view that lupus erythematosus is definitely due to a chronic streptococcic poisoning most frequently derived from the tonsils or teeth. Without being quite so precise as this, I may say that after many years of investigation I have no doubt that he is right in some cases. One of the difficulties of assessing the amount of skin

The great difficulty in naming a tumour endothelioma is to demonstrate its origin from endothelium, and it is practically impossible, as Du Bray and Rosson[1] point out, to eliminate the supposition that they are carcinomata originating from the lung epithelium, either alveolar or bronchial, as the tumours are never seen when confined purely to pleura and without having extended to some degree into the lung substance. Writers on histology [2] classify endothelium generally as pavement epithelium of mesoblastic origin, and there does not seem to be any satisfactory method of distinguishing this mesoblastic epithelium from the true epi- or hypoblastic type. Miller and Wynn [3] describe a case of endothelioma of the peritoneum in which, using Van Gieson stain, they demonstrate an apparent connexion between the processes of the epithelial-like cells and the fibrils of the stroma, and suggest that this points to a connective tissue origin. Adler [4] thinks they originate from the lining endothelium of the pleura, while Schultz and Eppinger believe that these tumours usually originate in the endothelium of the lymphatic vessels. Bloch[5] collected 63 cases, which he divided into two groups, the larger (47 cases) being endotheliomata, which he considers had origin in the endothelial lining of the pleura, and the smaller (16 cases) being spindle-celled sarcomata from the subjacent connective tissue. Adami [6] calls these tumours mesotheliomata, grouping them with epitheliomata as lining membrane growths, in this case of mesoblastic origin.

In the case described above the uniform growth—almost entirely confined to the pleura, with only slight and superficial involvement of the lung, and the general histological appearance—seem to indicate the endothelial lining cells of the pleura as the primary source, and so, adopting Adami's nomenclature, it would be called a mesothelioma. The general characteristics in this case correspond with most of those recorded, but it seems to be at a rather earlier stage. The age of incidence (Patterson[7]) is said to be usually between 40 and 60; the tumours are slightly more common in males than females, and are more often right-sided. They are frequently associated with profuse blood-stained exudate, although many cases are described in which the pleural cavity is completely obliterated with growth. Extension is usually by direct infiltration rather than by the blood stream.

We are much indebted to Dr. MacAlister for his help and for permission to publish this case, and to Mr. R. Gick for the drawing (Fig. 1) reproduced here.

A CASE OF
CURE OF DETACHMENT OF RETINA.

By ROBERT FOSTER MOORE, O.B.E., M.A.,
B.Ch. Cantab., F.R.C.S. Eng.,
URGEON, MOORFIELDS EYE HOSPITAL; ASSISTANT OPHTHALMIC
SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

My reasons for publishing a single case in which the complete disappearance of a detachment of the retina has followed a definite line of treatment are, on the one hand, that it is a condition in which almost entire loss of useful sight eventuates in all but a few cases, and, on the other hand, the great variety of forms of treatment advocated, is sufficient testimony to the unsatisfactory nature of the results obtained. My own experience of any form of operative treatment wh [illegible] for its object the evacuation of the sub- [illegible] l has been uniformly discouraging: and many cases are made worse by the procedure. I believe it is the general experience of ophthalmic surgeons, that when a patient has been confined to bed for a month—a course which is generally insisted on as auxiliary to any form of treatment—he usually says his sight is improved, although no alteration in the objective signs is detected, the detachment being as large as before.

There is one form of detachment from which recovery is almost invariable, and another which I believe to be so entirely hopeless that an attempt at treatment is not worth while. The former is that occurring as a complication of renal retinitis. In this condition, if extensive retinal changes are present, and especially in pregnancy cases, it is not rare to find retinal detachment occurring, from the transudation of fluid from the retinal tissues into the subretinal space. I found 13 such cases in two years in the medical wards of St. Bartholomew's Hospital.[1] If the patient survives, these detachments usually disappear quite quickly, and in any case no local treatment is called for. The second group consists of those cases in which it is known from ophthalmoscopic examination that a rent is present in the retina, so that the vitreous is free to invade the subretinal space; I believe such cases hold out no prospect of cure.

Other cases of what one may speak of loosely as primary retinal detachment come within the scope of our treatment, but good so seldom results that the prospect often seems hardly to justify the recommendation of a course of treatment which is somewhat tedious and prolonged.

For the last two years I have nevertheless admitted all such patients who were willing, and have treated them on the following lines. They have been confined to bed, and injections of 5 per cent. sodium chloride and 5 per cent. sodium citrate solutions, with the addition in each case of 4 per cent. novocain, have been injected, by means of a hypodermic syringe, in amounts of about 15 minims, under Tenon's capsule over the site of the detachment. The injections cause some local reaction, so that it is not found practicable to repeat them more often than about every third day—i.e., the sodium chloride is injected one day, and three days later sodium citrate; three days later again sodium chloride, and so on for nine or ten injections.

E. J., aged 44, attended at Moorfields on March 30th, 1921, because the sight of the left eye had failed for two months; he had always been short-sighted. He had a large transparent retinal detachment, and I admitted him for treatment. The following details are abstracted from the notes of Mr. E. F. Wilson, house surgeon at the hospital, by whom the treatment was carried out. "In the left eye is a large myopic complete crescent, and a large transparent retinal detachment down and out." The patient was admitted on April 1st, and a month's treatment on the above lines was carried out; on examination, when he was about again, the detachment had completely disappeared. Mr. Wilson's note of May 10th says: "Left eye quiet, pupil dilated; no detachment can be seen; field shows reduction of scotomatous area; few pigmentary changes down and out; V.R.−6=6/9; V.L.−7 =6/12."

Five of my colleagues were good enough to examine the man for me with the express intent of finding if possible any evidence of retinal detachment, and all were agreed that none was present. I do not claim any great originality for the line of treatment adopted, nor do I fail to appreciate that the condition may recur, but for myself I am encouraged to continue on this definite line of treatment, at a time when I had almost despaired of ever effecting any real good, and it is satisfactory to find justification for holding out some prospect of help for a condition looked upon as almost hopeless.

[1] Moorfields Eye Hospital Reports, vol. xx., Pt 2.

Liebig's Extract of Meat Company, Ltd.—The Board has resolved to recommend an increase in the Company's capital of an additional 180,000 new ordinary shares of £5 each, thus increasing the ordinary capital to 300,000 shares of £5 each.

"nervousness" has, perhaps, led the specialist in some cases to underestimate the influence of psychical states on the skin. I think, however, that one should approach this subject with critical reserve, and only after very careful examination of the evidence put down a dermatosis to psychical influence.

The dermatological world is very familiar with a series of eruptions, chiefly wheals, bullæ, abrasions, and ulcers, which have been described on the continent as due to the direct trophic action of a psychic influence. These diseases are not recognised in this country because in every case, as far as my knowledge goes, in which an apparent instance has been encountered careful observation and investigation have established the fact that although no doubt a psychic influence has been at work, the actual eruption has been produced by the self-infliction of injury, and the cases are therefore classified here under the heading of "feigned eruptions." In some of these cases the eruption has been produced deliberately, and during the late war a new, or at least an unfamiliar, dermatosis of a pustular nature appeared in unwilling conscripts, and I have heard that there was an establishment somewhere in London where one could take lessons in the art of its production. Certainly I was deceived by the first case I saw and put it down to the effect of sweating in a coarse woollen shirt and the carrying of a pack. Later on I became familiar with it, as did many of my colleagues in the specialty.

In other cases I am pretty confident that patients produce the eruption in a state of mind that I believe would be classed under the heading of dissociation, and are not aware of their own behaviour. Dr. Pernet advanced this view of double personality some time ago. Putting these locally produced eruptions aside, there undoubtedly remain others, though the mechanism of their production is obscure.

To begin with, we may note that in female patients there is an eruption called erythema pudicitiæ which is clearly nervous in origin. On exposing the trunk of the patient a lenticular erythema is seen on the chest and shoulders, and this fades gradually away. It is not due to change of temperature, as it is often seen immediately the dress is undone and before the chilling has come into action. The eruption is quite common, and its only interest, as far as I am concerned, lies in the fact that it is produced by a psychic influence. If congestive erythema may be thus produced it seems not unlikely that a more serious eruption may also result if the psychic disturbance be more pronounced or prolonged.

It is not so very uncommon for very nervous patients to suffer from so-called "dead finger," and to state that this condition may be brought on by their being startled.

Within the last few years I have had such a patient in my room, and while questioning her I contrived to upset a heavy tray of notes on to the floor so as to make a sudden and considerable noise. In a short time three of her fingers, two on the left hand and one on the right slowly became ivory white. More prolonged circulatory disturbances might, I think, lead to persistent affection of the skin, and I have, I believe, instances of the kind. One was the case of a lady who was not at all well off, whose sons in turn as they grew older competed for scholarships which meant a great deal to her. As the critical time approached she had attacks of weeping eczema on the fingers, and these subsided after the results were known. I saw her during one of the attacks and was unable to do more than palliate it until the period of suspense was over.

Another patient, also a lady, lived in a town over which hostile aeroplanes were frequently passing during the war. She was very stouthearted, and as her husband was obliged to live there she refused to leave. At first all went well, but after a time bouts of nocturnal firing by our guns and the dropping of bombs by hostile aeroplanes were followed by an acute outbreak of vesicular eczema on the face and hands. Later still if her baby cried in the night she woke startled and the eczema soon reappeared. I then persuaded her to leave and go inland, where the whole trouble disappeared in a short time.

It must, I think, be in the common knowledge of all of us that alopecia areata was much more frequent during the war, and not only in those in the army. To so great an extent was this the case that a witty colleague christened it "alopecia airraider." This is to me a matter of interest, as I have always held the trophoneurotic theory of this disease, and this fact seems to me to be difficult to reconcile with Dr. Barber's theory that alopecia areata is due to septic absorption from gums or tonsils.

Dr. Vigulo-Lutati[22] has also published a series of cases of somewhat similar nature in the Italian army.

The hair of an artillery captain, 24 years of age, turned almost completely white during the two days of the battle on the Piave. A young lieutenant had barely escaped being taken prisoner by the enemy and part of the hair on one side turned white in a day or two. In another case a railroad man of 38, after a bombardment of his train, had all the hair of his head, eyebrows, and beard drop out. As it grew again it came in white, but by the end of eight months the eyebrows and beard had returned to the former chestnut colour, while the scalp hair still remained white. Another soldier noticed a long patch of white hairs on the side of his head the morning after a battle. This white strip was still obvious eight months later when Lutati first saw him.

Other cases of premature blanching have been observed. Cases of this kind seem to suggest a direct psychic influence on the skin, but I am of opinion that it is not infrequent for the mental condition to act indirectly on the skin.

One cannot deal with large numbers of patients suffering from those skin diseases such as urticaria, dermatitis herpetiformis, eczema, and psoriasis, in which, at all events, up to the present no one specific cause is known, without being struck by the frequency with which one gets a history of mental shock or overstrain. Of course, one must be on one's guard against the too ready acceptance of the patient's story, as in the case mentioned earlier in these lectures in which an eczema ascribed by the patient to worry and overwork proved on investigation to be due to the poison of *Rhus toxicodendron*, but after one has used the utmost care there remains a number of cases which, at all events, get better or worse according to the mental condition of the patient.

We are all, I suppose, familiar with the great influence of the mental condition over the state of the digestive functions, including both secretion and motility, and I venture to think that it is through these vital processes that the mental condition sometimes acts indirectly. As a further instance of the relationship between the central nervous system and the skin I may mention lichen planus. For very many years there have been numerous expert dermatologists, among others the late Dr. Colcott Fox, who were convinced that there was a close relationship between lichen planus and the nervous system. This idea owed its origin, I think, to the frequency with which this disease was associated with a history of sudden shock or prolonged nerve strain. No further convincing evidence was obtained for some time.

Then Drs. Thibierge and Ravaut[23] drew off some of the cerebro-spinal fluid by means of lumbar puncture. Nothing abnormal was found in the pressure or the constitution of the fluid, but the eruption was very favourably influenced by the procedure. This operation has been repeated by several observers, and in one case Dr. Pernet[24] obtained a fluid which did not reduce Fehling's solution. My own experience of this method has been almost entirely favourable. The worst case that I have treated had a nearly universal eruption which was so intensely irritable that she had been almost sleepless for three weeks. Relief from the itching and consequent return of sleep were secured within 48 hours, and the eruption began to flatten in a few days. Fourteen days after the removal of about 8 c.cm. of cerebro-spinal fluid she left the hospital in good health, and with only a widespread brown pigmentation to mark the distribution of her previous eruption. I am of opinion that in this case the procedure saved her reason, if not her life.

In all cases so treated by me the effect on the subjective symptoms has been dramatic, and in all but two the eruption has lost its infiltrative character soon after the withdrawal. In one of these two

The great difficulty in naming a tumour endothelioma is to demonstrate its origin from endothelium, and it is practically impossible, as Du Bray and Rosson[1] point out, to eliminate the supposition that they are carcinomata originating from the lung epithelium, either alveolar or bronchial, as the tumours are never seen when confined purely to pleura and without having extended to some degree into the lung substance. Writers on histology[2] classify endothelium generally as pavement epithelium of mesoblastic origin, and there does not seem to be any satisfactory method of distinguishing this mesoblastic epithelium from the true epi- or hypoblastic type. Miller and Wynn[3] describe a case of endothelioma of the peritoneum in which, using Van Gieson stain, they demonstrate an apparent connexion between the processes of the epithelial-like cells and the fibrils of the stroma, and suggest that this points to a connective tissue origin. Adler[4] thinks they originate from the lining endothelium of the pleura, while Schultz and Eppinger believe that these tumours usually originate in the endothelium of the lymphatic vessels. Bloch[5] collected 63 cases, which he divided into two groups, the larger (47 cases) being endotheliomata, which he considers had origin in the endothelial lining of the pleura, and the smaller (16 cases) being spindle-celled sarcomata from the subjacent connective tissue. Adami[6] calls these tumours mesotheliomata, grouping them with epitheliomata as lining membrane growths, in this case of mesoblastic origin.

In the case described above the uniform growth—almost entirely confined to the pleura, with only slight and superficial involvement of the lung, and the general histological appearance—seem to indicate the endothelial lining cells of the pleura as the primary source, and so, adopting Adami's nomenclature, it would be called a mesothelioma. The general characteristics in this case correspond with most of those recorded, but it seems to be at a rather earlier stage. The age of incidence (Patterson[7]) is said to be usually between 40 and 60; the tumours are slightly more common in males than females, and are more often right-sided. They are frequently associated with profuse blood-stained exudate, although many cases are described in which the pleural cavity is completely obliterated with growth. Extension is usually by direct infiltration rather than by the blood stream.

We are much indebted to Dr. MacAlister for his help and for permission to publish this case, and to Mr. R. Gick for the drawing (Fig. 1) reproduced here.

A CASE OF
CURE OF DETACHMENT OF RETINA.

BY ROBERT FOSTER MOORE, O.B.E., M.A.,
B.CH. CANTAB., F.R.C.S. ENG.,

SURGEON, MOORFIELDS EYE HOSPITAL; ASSISTANT OPHTHALMIC SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

MY reasons for publishing a single case in which the complete disappearance of a detachment of the retina has followed a definite line of treatment are, on the one hand, that it is a condition in which almost entire loss of useful sight eventuates in all but a few cases, and, on the other hand, the great variety of forms of treatment advocated, is sufficient testimony to the unsatisfactory nature of the results obtained. My own experience of any form of operative treatment which has for its object the evacuation of the subretinal fluid has been uniformly discouraging; and many cases are made worse by the procedure. I believe it is the general experience of ophthalmic surgeons, that when a patient has been confined to bed for a month—a course which is generally insisted on as auxiliary to any form of treatment—he usually says his sight is improved, although no alteration in the objective signs is detected, the detachment being as large as before.

There is one form of detachment from which recovery is almost invariable, and another which I believe to be so entirely hopeless that an attempt at treatment is not worth while. The former is that occurring as a complication of renal retinitis. In this condition, if extensive retinal changes are present, and especially in pregnancy cases, it is not rare to find retinal detachment occurring, from the transudation of fluid from the retinal tissues into the subretinal space. I found 13 such cases in two years in the medical wards of St. Bartholomew's Hospital.[1] If the patient survives, these detachments usually disappear quite quickly, and in any case no local treatment is called for. The second group consists of those cases in which it is known from ophthalmoscopic examination that a rent is present in the retina, so that the vitreous is free to invade the subretinal space; I believe such cases hold out no prospect of cure.

Other cases of what one may speak of loosely as primary retinal detachment come within the scope of our treatment, but good so seldom results that the prospect often seems hardly to justify the recommendation of a course of treatment which is somewhat tedious and prolonged.

For the last two years I have nevertheless admitted all such patients who were willing, and have treated them on the following lines. They have been confined to bed, and injections of 5 per cent. sodium chloride and 5 per cent. sodium citrate solutions, with the addition in each case of 4 per cent. novocain, have been injected, by means of a hypodermic syringe, in amounts of about 15 minims, under Tenon's capsule over the site of the detachment. The injections cause some local reaction, so that it is not found practicable to repeat them more often than about every third day—i.e., the sodium chloride is injected one day, and three days later sodium citrate; three days later again sodium chloride, and so on for nine or ten injections.

E. J., aged 44, attended at Moorfields on March 30th, 1921, *because the sight of the left eye had failed for two* months; he had always been short-sighted. He had a large transparent retinal detachment, and *I admitted him* for treatment. The following details are abstracted from the notes of Mr. E. F. Wilson, house surgeon at the hospital, by whom the treatment was carried out. "In the left eye is a large myopic complete crescent, and a large transparent retinal detachment down and out." The patient was admitted on April 1st, and a month's treatment on the above lines was carried out; on examination, when he was about again, the detachment had completely disappeared. Mr. Wilson's note of May 10th says: "Left eye quiet, pupil dilated; no detachment can be seen; field shows reduction of scotomatous area; few pigmentary changes down and out; V.R. – 6 = 6/9; V.L. – 7 = 6/12."

Five of my colleagues were good enough to examine the man for me with the express intent of finding if possible *any* evidence of retinal detachment, and all were agreed that none was present. I do not claim any great originality for the line of treatment adopted, nor do I fail to appreciate that the condition may recur, but for myself I am encouraged to continue on this definite line of treatment, at a time when I had almost despaired of ever effecting any real good, and it is satisfactory to find justification for holding out some prospect of help for a condition looked upon as almost hopeless.

LIEBIG'S EXTRACT OF MEAT COMPANY, LTD.—The Board has resolved to recommend an increase in the Company's capital of an additional 180,000 new ordinary shares of £5 each, thus increasing the ordinary capital to 300,000 shares of £5 each.

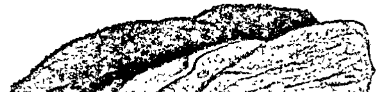
needle was inserted at once, and 21 ounces of clear straw-coloured fluid were aspirated off (needle then got blocked). The next day there was a slight hyper-resonance above the third rib on the right side, but the cardiac apex beat remained in exactly the same position as before, and patient did not seem much relieved. On Jan. 31st patient was X rayed to see whether there was any aneurysm, but nothing suggestive of that condition appeared on the plate. On Feb. 3rd the right side of the chest was again dull up to the clavicle, and 30 ounces of the same light yellow fluid were withdrawn. Still the apex beat remained in the same position. A blood test of this date showed that the Wassermann reaction was negative. Patient was aspirated again on Feb. 10th and 13th, and on the latter occasion the fluid withdrawn was blood stained. The diagnosis was now put forward that a growth was pressing on the superior vena cava and coming towards the surface at the left border of the sternum, thus fixing the mediastinum and therefore the apex beat, but it was not suspected that the site of the growth was in the pleura. After this an attempt was made to allow the fluid to drain away continuously by inserting a Southey's tube in the axilla and afterwards in the back, but the tube did not tap the fluid unless it was held firmly pushed in up to the guard, and it was found impossible to keep it in this position.

Between Jan. 29th and Feb. 18th 200 ounces of fluid had been withdrawn altogether, and the right pleural cavity was still three-quarters full, and the position of the apex beat unchanged. The tender spot was still present at the border of the sternum. The general condition of the patient had not altered, except that he had become weaker; his temperature ranged between 98° and 99° F.; pulse 104 to 120; respiration rate 28 to 38 per minute. A swelling of firm consistence, apparently due to distortion of the thoracic wall, had gradually developed on the right side just below the angle of the scapula; the ribs seemed to have come closer together at this place, so that it was hard to insert a trocar between them.

Aspiration was repeated on Feb. 22nd and 25th, and March 5th, as much as 70 ounces of deeply blood-stained fluid being withdrawn on the last two occasions, and then the aspiration was stopped, each time because patient began to cough. From the beginning of March the lower lobe of the left lung began to be œdematous, and patient became more breathless and often delirious. He began to complain of pain along the right costal margin and in the right side of the abdomen, and the skin was hyperæsthetic in the same area; this was thought to be due to pressure on intercostal nerves in the swelling posteriorly.

He died suddenly on the morning of March 12th, six weeks from the date of his admission and 11 weeks from the onset of symptoms.

FIG. 1.



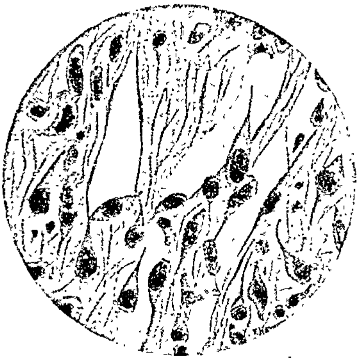
Drawing of posterior aspect of tumour.

Post-mortem Findings.

The autopsy was performed 18 hours after death. P.M. lividity and rigidity normal; body fairly well nourished. A small tumour was felt on anterior thoracic wall, not attached to skin, at the level of the fourth intercostal space, just internal to right nipple line. On opening thorax a growth was found which took the form of a massive nodular thickening of the parietal pleura lining the whole of the ribs, costal cartilages, sternum, and diaphragm on the right side, and which to some extent had spread on to the visceral pleura at the root and base of right lung. The nodules varied in size from that of a pea to a hazel nut, the larger being umbilicated. The greatest thickness of growth, amounting to about ¾ inch, was in the region of the angles of the eighth to eleventh ribs.

The space between lung and tumour contained about two quarts of blood-stained fluid. There were no bands or adhesions. The right lung was collapsed and fibrous, and except at the base and root was covered with thickened pleura which was apparently inflammatory and not new growth. At its base the lung had been superficially infiltrated with growth, which formed a nodular layer about ⅛ inch to ¼ inch thick. The growth had extended between the fourth and fifth ribs on the right side to form a subcutaneous swelling above noted, but had not infiltrated the bone or cartilage. The left pleura and lung were normal, except for a few superficial scattered nodules of growth on the visceral pleura and a slight degree of emphysema of the lung. The mediastinal glands were somewhat enlarged, and were found to be heavily infiltrated with growth.

FIG. 2.



High-power drawing to illustrate type of cell; magnification, 600.

The parietal pericardium at its upper end was invaded with nodules, which had not extended to the visceral layer, but were of sufficient bulk to cause compression of the superior vena cava and the coronary veins, the latter being dilated and somewhat varicose. The heart itself was normal, except for its position, which was well to the left of normal. The trachea and bronchi were opened up as far as possible, but no growth was found, and the œsophagus was normal. The peritoneum showed no evidence of growth. The liver was large (88 ounces) and pale, showing slight chronic venous congestion, and was displaced downwards, the lower margin being 3 inches below costal margin. All other organs were normal except for slight congestion, and showed no primary or secondary tumour formation. The mesenteric glands in the region of the solar plexus were somewhat enlarged.

Microscopic Appearances.

Histologically the tumour consisted of a fibrous tissue stroma in which were seen epithelial-like cells of rather polymorphous appearance, varying according to their situation from round, flat cells, indistinguishable from squamous epithelium, to pear-shaped or spindle-shaped forms. Some of these cells appeared to be branched, and on staining with Van Gieson in some places the "tails" seemed to be continuous with the fibrils of the stroma. The nuclei were rounded and uniformly rich in chromatin, but mitotic figures were rare. The cells were grouped in columns or clumps, but no definite alveolar arrangement could be made out. The very few blood-vessels seen were mostly well formed. In sections through the main growth (i.e., from upper surface of diaphragm) the cells were more spindle-shaped, and the fibrous stroma more abundant, whereas in some of the superficial alveoli of the base of the lung and in the mediastinal lymphatic glands masses of tumour cells with little or no stroma were found, and the cells were much more spherical.

Remarks on the Case.

The true nature of these tumours of the pleura has been the subject of much controversy, as is seen by the variety of names given to them—e.g., endothelial cancer, sarco-carcinoma, alveolar endothelial sarcoma, mesothelioma, and so on.

the air bag is fastened to the urethroscope by means of a piece of fine wire and that the connexion between the cannula and the urethroscope is in order and secure. An excellent plan is to practise on an artificial urethra in the shape of a piece of white rubber tubing a size or two larger than the cannula, which should engage it quite loosely.

To anæsthetise the urethra 10 drops of a 1 per cent. solution of cocaine hydrochloride injected into the canal and held in for three or four minutes is sufficient. The cocaine may be dissolved in a 1 in 2000 mercury oxycyanide solution. The injected fluid should not be forced down into the bulbo-membranous region, or the air on inflation will pass too readily through this part into the bladder.

Modifications of the Urethroscope.

Apart from the new operating tubes the body of the urethroscope has been remodelled, but ability to operate through the open cannula without air distension, as in the case of the posterior urethra, is retained as a feature of the instrument.

The mechanism, by means of which nozzle and cannula can be moved further away from the body of the urethroscope, so as to allow room for the play of the handle of an instrument when used through the open tube without air distension, has been accomplished by making the horizontal bar which carries the nozzle reversible. Likewise the head or hood which carries the mirror can be turned back, as in previous models, to facilitate the introduction of an instrument into, and its removal from, the cannula when used in similar circumstances.

The focussing arrangement has been improved and simplified. It is, however, essential, as in the old model, to focus the light from the tri-filament lamp *before* the mirror has been placed in position in front of the lens. To do this, turn back the hood which carries the mirror out of the way, point the bull's eye lens to some white object about nine inches from it, and move the lens by the means provided until the limbs of the star-shaped light are about half an inch wide at the middle where they cross. It is only the small central area of light which is reflected down the cannula, the limbs of the "star" being simply lost. Care should be taken that this central area of light is as perfect as possible and no larger than a threepenny piece. When the mirror has been placed in position in front of the lens by replacing the hood it can be manipulated by two movements, so as to direct the beam of light accurately down the urethral tube. In the first place it can be moved around a vertical axis by rotating the inner cylinder into which it is fixed, and secondly, around a horizontal axis by means of a thumb screw. The rotation of the cylinder is controlled by a binding screw. These focussing details should always be attended to before the instrument is used on a patient.

The switch for the light can be operated with one hand—a point of importance. The telescope, which is now screwed into the centre of the cylinder forming the head, is more easily made in correct alignment with the urethral cannulæ than was formerly the case. The glass window of the air-chamber has been brought right up to the mirror and is surrounded by the cylindrical head. This effectually prevents all reflections of light from extraneous sources which formerly were very annoying. Operating cannulæ are now fitted with a binding screw, making its connexion with the nozzle of the urethroscope secure.

Principal Instruments.

The following is a list of the principal instruments made: those marked with an asterisk are supplied as a standard set by the manufacturers with the new urethroscope:—

*1. Probes for caustic and one long exploratory. *2. Knife. *3. Blunt spoon. *4. Curette. *5. Probe, sharp, for electrolysis. *6. Capillary syringe. 7. Forceps. 8. Snare. 9. Cautery. 10. Flexible metal bougie. 11. Filiform gum-elastic bougie. 12. Probe and cautery for use with the open prostatic tube.

The examining cannulæ, which are five inches long, are supplied in four sizes—viz., 20, 22, 24, and 26 of the French scale. The operating tubes are supplied in three sizes—viz., 22 F, 24 F, and 26 F. They are four inches long, but any size and length can be obtained by a special order.

Notes on the Use of Some of the Instruments.

Caustic probe.—This instrument is chiefly for the cure of chronic suppurating lacunæ. The probe is projected for three-quarters of an inch beyond the end of the cannula, heated in a spirit flame or Bunsen burner, and a very thin layer of lunar caustic melted on to the terminal quarter of an inch. It is then withdrawn into its sheath. The cannula should be passed to its full extent before the urethra is inflated and the probe projected, which should only be to the extent of half or three-quarters of an inch. The sheath with its contained probe should lie over the affected lacunæ. These can be probed as they come into view while the cannula is slowly withdrawn, its distal end being slightly tilted towards the lacunæ. If the projected part of the probe is not well seen on looking down the cannula it must be slightly bent, before it is used on the patient, to bring it well into view.

Electrolytic needle.—This needle, connected with the negative pole of the battery, is used for cauterising the small superficial infected and swollen follicles so commonly found in the non-gonococcal variety of urethritis. The follicle is punctured or is entered through its natural outlet. The operation is performed across the urethra and the terminal half inch of the needle must be bent up to bring it well into view. Three to five milliamperes may be used for from five to 20 seconds in each affected follicle. Cysts and large inflamed glands of Littre may also be treated in this way.

Capillary syringe.—This is used for syringing out fistulæ, &c., also for treating the large lacunæ if milder treatment than the caustic probe is indicated. Care must be taken not to penetrate the mucous membrane and inject the fluid into the submucous tissues. A rubber teat may be used instead of a small (hypodermic) syringe. The distal end of the syringe should be bent up a little to bring it into view when looking down the cannula.

Blunt spoon.—This may be used for milking and collecting the discharge from infected lacunæ, sinuses, &c., for bacteriological purposes. In this way it will be found valuable in the treatment of gonorrhœa.

Curette.—For use in wart and polypus cases, and as a substitute for the end of the cannula, for scraping off the heaped-up necrosed epithelium which covers some chronic and sclerosed patches. A dab of silver nitrate solution, 20 grains to the ounce, should follow this treatment, and subsequently dilatation of the canal. Care must be taken not to cut through the mucous membrane with a sharp curette.

Knife.—The fear of admitting air into the cellular planes or into the circulation itself deters the cautious from making a deep incision into the urethral wall in the inflated condition. Were it not for this fear a large number of cases of isolated strictures could be easily and accurately cut under control of the eye. Until the subject has been worked out the use of the knife must be confined to such small undertakings as the division of superficial bands, congenital or otherwise, incising small abscesses and cysts, or slitting up sinuses.

Cautery.—Sometimes useful in cases of warts, polypi, and cysts, and for endeavouring to seal up the internal orifice of a fistula. Being a powerful means of treatment great care should be exercised in its use. For instance, if used for the cure of suppurating lacunæ the little cavities which result harbour a drop of mucus which appears at the meatus on stripping the urethra, much to the annoyance of the patient.

Fine-wire snare.—This instrument will perhaps be occasionally required for polypus cases.

I am indebted to the Genito-Urinary Manufacturing Co., Ltd., and to Messrs. Allen and Hanburys, Ltd., for the care and skill they have shown in the manufacture of all these instruments.

LITERARY INTELLIGENCE.—Messrs. William Heinemann (Medical Books), Ltd., announce the forthcoming publication of the following: Special Pathology, second edition, by Dr. J. Martin Beattie and Dr. W. E. Carnegie Dickson. The Surgical Exposure of the Deep-seated Blood-vessels, by Dr. J. Fiolle and Dr. J. Delmas, translated and edited by Dr. C. G. Cumston, with a preface by Sir D'Arcy Power. The Surgical Treatment of Non-malignant Affections of the Stomach, by Dr. C. G. Cumston and Dr. George Patry, with an introduction by Sir Berkeley Moynihan.

OPERATIVE URETHROSCOPY:

AN IMPROVED URETHROSCOPE.

By W. WYNDHAM POWELL, F.R.C.S. Eng., L.R.C.P. Lond.,

LATE SURGEON TO THE WESTMINSTER GENERAL DISPENSARY.

For a long time I have been engaged in an endeavour to simplify the method of operating in the anterior urethra under air-distension. The variety of instruments on the market show that a satisfactory solution of the problem has not yet been attained. The former difficulties of operating may be summed up under two heads. In the first place means had to be found for retaining the air in the urethra while the instrument was in use, and secondly, the long shaft of the instrument had to be made sufficiently slender not to interfere unduly with the view, or, also, with the illumination when an external light was used. The chief defect was associated with the length of the shaft of the operating instrument, the weakness of which was fatal to all but the most trivial undertakings. That these difficulties have now been satisfactorily overcome, I venture to submit, will be apparent from the following description of the new instruments.

To put it very simply the scheme has been to affix to the distal end of the urethroscopic tube or cannula a short instrument by means of which a small operation can be performed exactly under the same conditions as apply to an ordinary urethroscopic examination. By using the urethroscope as the handle and the cannula itself as the shaft of the instrument, the former long, weak intra-urethral operating instrument is replaced by a powerful one with practically no obstruction to the view.

The scheme involved two problems, which were solved by one device. In the first place the urethra had to be guarded against accidental injury, and secondly, means had to be found for varying the length of that part of the instrument which jutted out beyond the end of the cannula. I found that by housing the long, slender shaft of the intra-urethral operating instrument in a tiny tube or sheath, fixed to either the inner or outer wall of the cannula, and extending from the flange to the distal end, the necessary means for protruding it beyond the end of the cannula and for withdrawing it into the shelter of the tube were secured. Owing to the support which the sheath gives to the shaft and to the insignificant work required of the latter where enclosed and supported by the sheath, only a slender and pliable steel wire is necessary. The distal end, however, requires more rigidity; but as it is necessary to project the instrument for operative work only to the extent of about half an inch beyond the end of the sheath and cannula a very little increase in thickness of this part is sufficient to meet any ordinary strain.

The sheath and its contained pliable shaft, tracing them outwards, leave the cannula altogether at the flange, and terminate away from the line of vision. A small cap, with rubber disc, through which the shaft passes, is fixed to the outer end of the sheath and prevents the escape of air from the urethra by this route. A tiny sleeve-like handle, fitted with a binding screw, can be slipped over the end of the shaft and fixed in any position, controlling the distance to which the instrument can be projected beyond the end of the cannula.

Method of Use.

The urethroscope and cannula with its contained operating instrument are used as one implement with one hand, the other hand, after projecting the operating instrument into the inflated urethra, being left free for other purposes. The operation is performed by moving the cannula in the urethra, and not by moving the stem of the instrument in its sheath, which it fits firmly. The cannula, therefore, must not engage the urethra too tightly.

Even when a filiform bougie or a long silver exploratory probe is used through the sheath it is usually better to push it well beyond the end of the cannula into the inflated urethra and to use it by manipulating the whole apparatus in the usual way. By this method it is easy to catheterise Cowper's ducts when the orifices can be made out. It will be noticed that as the cannula is made to serve the joint purposes of urethroscopy and instrumentation the light during the various movements will automatically follow the point of the instrument, and will at the same time be invariably directed to the spot that is being operated upon.

Owing to the mobility of the parts the oblique end of the cannula can be directed to any section of the urethral wall by tilting the urethroscope, and the least protrusion of the instrument beyond the end of the tube will bring it into relationship with the mucous membrane. An instrument must not be projected beyond the end of the cannula into the urethra until the latter has been inflated, and then only under direct control of the eye, and at the completion of the operation it must be withdrawn into the shelter of the cannula before the urethra has been emptied of air or the cannula removed.

Most instruments are designed to operate across the urethra. If, for instance, a knife in its sheath runs along the wall of the cannula, which is in contact with the floor of the urethra, the incision will take place on the roof of the canal. The snare, and the probe, when used for cauterising the lacuna, will, however, be placed and used on the same side as the lesion. Reference to the illustrations (A and B) will demonstrate this better than can be explained by words.

Sheathing of the Instruments.

Instruments, such as the knife and curette, which have an enlarged operating end must be introduced into position in the sheath from the far end of the cannula; some of the others, such as the capillary syringe, must be sheathed from the proximal end. The selected instrument must be in position in its sheath before the cannula is inserted into the urethra, and the little handle fixed in position for a half-inch projection.

Before use a little sterile vaseline may be smeared on the shaft of the instrument. After use it should be withdrawn from its sheath and thoroughly dried before putting away. A disc, in the absence of proper packing, may be improvised from a rubber glove or tube. It is essential when using a cutting instrument to maintain uninterruptedly the inflation of the urethra. Therefore, see that the tubing from although gangrene often resulted. (3) Artificial respiration was useful in colubrine bites, if an antidote was available to neutralise the venom after its absorption. (4) Incision and forcible expression of the venom, cauterisation, electrolysis, bleeding, and saline perfusion were measures of but little avail. He then estimated the value of certain chemical remedies.

About 200 chemical reagents had been tested, and those found to neutralise venoms *in vitro* were numerous. (1) The action of tissue extracts, bile, and ferments was slow and weak; (2) caustics acted solely by causing proteid coagulation. (3) Oxidising agents—e.g., chlorates, permanganates, hydrogen peroxide, and antiseptics were only weak antidotes; (4) soluble salts of heavy metals—e.g., chlorides of gold, platinum, palladium, mercury, zinc, and silver provided most hope of effective remedy by chemical means. The value of local remedies was limited by and dependent on two factors: (*a*) the necessity of injection before a fatal dose of venom had been absorbed into the general circulation—in the case of cobra venom, this period for man was about 15 minutes, a time limit which was increased by effective ligature; (*b*) their capacity only of destroying the venom with which they came in contact at the seat of injection, provided an efficient ligature had been applied. The subcutaneous injection of chemical antidotes gave better results than did incision and rubbing in moistened crystals. Major Knowles referred to the failure of the Lauder Brunton technique with potassium permanganate crystals and to the greater efficacy of forcible injection into the tissues at the seat of the bite, particularly in the use of zinc permanganate solution. Iodine tetrachloride and other known remedies had proved less satisfactory, but immediate subcutaneous injection of 10–20 c.cm. of 1 to 5 per cent. solution of gold chloride was more reliable than any other form of local remedy. Its neutralising effect was greater when brought in contact with larger doses of venom in concentrated solution, than on small doses in dilute solution. Intravenous injection of chemical solutions was useless. The value of all local remedies was greater in the case of viperine than of colubrine bites. They acted by causing local coagulation necrosis, destroying both tissues and venom, and so were productive of local gangrene. After the lapse of 15 minutes from the bite—that is, when one M.L.D. of venom had been absorbed—it was necessary to supplement local by systemic remedies. Thence had originated that important section of their work dealing with the study of antivenene.

Antivenene.

To Calmette the world was indebted for the introduction of this very promising method of treatment. Calmette's observations, however, had led to the erroneous conclusion that a cobra did not inject more than 20 mgm. of desiccated venom at a good bite. This their own experiments had disproved, for as already stated, there might be a yield of anything from 0 to 570 mgm. of venom from a single bite. Calmette had also regarded 1 c.cm. of antivenene *in vitro* as neutralising 1 mgm. of desiccated cobra venom. Their results with rats had clearly established this to be a considerable underestimate, for they had found that the *in vivo* value of 1 c.cm. of antivenene was only equal to $\frac{1}{10}$ mgm. of desiccated venom. The antivenene now in use in India was all prepared at Kasauli by immunising horses against the venoms of the cobra and Russell's viper. It was strictly specific and experimentally was incapable of neutralising other colubrine or other viperine venoms. Its potency, however, was weak and diminished on keeping. Improved results could be obtained, firstly, by altering the mode of administration, the intravenous method being more effective than the intraperitoneal, and the latter than by hypodermic injection: secondly, by securing a concentrated antivenene by methods analogous to those for the concentration of antidiphtheritic serum. This had eventually been arrived at after two years' experimental work at immunising the antivenene animals for colubrine and viperine venoms and by testing the various methods of serum concentration. The final product realised a potency twelve and a half times as great as the original sample. Major Knowles then explained the action and properties of antivenene and nature of the venom—antivenene complex. He said that the concluding part of their work at Kasauli in August, 1914, was concerned with the immunity of the cobra to its own venom, and with the endeavour to discover some antivenomous tissue extract in a cobra, which they had only succeeded in killing after intraperitoneal injection of as much as $\frac{3}{4}$ g. of desiccated venom. The bile alone showed any antivenomous activity, but was inferior in that respect to ox-bile. The cobra's immunity to its own venom was regarded, from the result of their observations, as probably due to a deficiency of the necessary complement.

Summarising the treatment called for in a case of snake-bite the following steps were recommended by Major Knowles: 1. Instant firm ligature to the limb above the site of the wound; 2. Killing and identification of the snake—(*a*) if non-poisonous, no further steps would be required; (*b*) but if one of the small vipers, a dose of calcium lactate might be given, the ligature removed and the patient watched; (*c*) if, however, the bite had been caused by one of the six really lethal Indian snakes, on the toe or finger, amputation might be advisable, but with the bite elsewhere than on the toe or finger forcible subcutaneous injection of gold chloride solution should be made into the site of the wound in order to isolate and destroy the whole dose of venom, but previous incision was not called for; (*d*) in the case of bite from a cobra or Russell's viper, 100-200 c.cm. of antivenene should be given intravenously, but if injected hypodermically three or four times that quantity would be necessary. On removal of the ligature after 20 minutes, careful watch over the patient was most essential, with a view to injecting more antivenene, and applying artificial respiration as well as the administration of cardiac stimulants. In the case of viper bites hæmorrhages might be expected after the lapse of hours or days from the time of the bite. He concluded it should be possible to save 80 per cent. of all cases of lethal snake-bite, if those remedies were available and were used sufficiently early. The prospects of finding a safe and reliable remedy against the bite of the most poisonous colubrine snakes were encouraging. The dichloride of palladium had proved, experimentally, even more efficacious than the gold salt, and it was possible that the palladium salt, by forming a new compound of heavy metallic ion with the antivenom, suitable for solution and for intravenous injection, might provide the desired remedy.

Discussion.

Sir LEONARD ROGERS, who had been interested in the subject of snake-bite and its treatment for the past 20 years, referred to early work of his on the physiological action of different classes of snake venoms published in the Philosophical Transactions of the Royal Society in 1904. He had dealt with the venoms of the cobra, king cobra, common krait, and banded krait, which produced respiratory failure. The venom of sea snakes, or *Hydrophineæ*, was very toxic and also caused respiratory failure. In connexion with viperine venoms he mentioned the work of Weir Mitchell as having proved their hæmorrhagic action and some vasomotor paralysis. As had been shown by Lamb, intravascular clotting was caused by the venom of Russell's viper. Describing his own observations, with a M.L.D. of viperine venom a rapid fall in blood pressure had been obtained, followed by respiratory convulsions and then a rise in blood pressure. *Post-mortem* examination had shown no intravascular clotting either in animals or man, and the blood was incoagulable. The fall in blood pressure was at first difficult to explain and was found to be due to vasomotor paralysis. Moreover, there was no clotting even in the pulmonary capillaries. On division of the spinal cord in an animal experiment there followed a fall

OPERATIVE URETHROSCOPY:

AN IMPROVED URETHROSCOPE.

BY W. WYNDHAM POWELL, F.R.C.S. ENG., L.R.C.P. LOND.,
LATE SURGEON TO THE WESTMINSTER GENERAL DISPENSARY.

FOR a long time I have been engaged in an endeavour to simplify the method of operating in the anterior urethra under air-distension. The variety of instruments on the market show that a satisfactory solution of the problem has not yet been attained. The former difficulties of operating may be summed up under two heads. In the first place means had to be found for retaining the air in the urethra while the instrument was in use, and secondly, the long shaft of the instrument had to be made sufficiently slender not to interfere unduly with the view, or, also, with the illumination when an external light was used. The chief defect was associated with the length of the shaft of the operating instrument, the weakness of which was fatal to all but the most trivial undertakings. That these difficulties have now been satisfactorily overcome, I venture to submit, will be apparent from the following description of the new instruments.

To put it very simply the scheme has been to affix to the distal end of the urethroscopic tube or cannula a short instrument by means of which a small operation can be performed exactly under the same conditions as apply to an ordinary urethroscopic examination. By using the urethroscope as the handle and the cannula itself as the shaft of the instrument, the former long, weak intra-urethral operating instrument is replaced by a powerful one with practically no obstruction to the view.

The scheme involved two problems, which were solved by one device. In the first place the urethra had to be guarded against accidental injury, and secondly, means had to be found for varying the length of that part of the instrument which jutted out beyond the end of the cannula. I found that by housing the long, slender shaft of the intra-urethral operating instrument in a tiny tube or sheath, fixed to either the inner or outer wall of the cannula, and extending from the flange to the distal end, the necessary means for protruding it beyond the end of the cannula and for withdrawing it into the shelter of the tube were secured. Owing to the support which the sheath gives to the shaft and to the insignificant work required of the latter where enclosed and supported by the sheath, only a slender and pliable steel wire is necessary. The distal end, however, requires more rigidity; but as it is necessary to project the instrument for operative work only to the extent of about half an inch beyond the end of the sheath and cannula a very little increase in thickness of this part is sufficient to meet any ordinary strain.

The sheath and its contained pliable shaft, tracing them outwards, leave the cannula altogether at the flange, and terminate away from the line of vision. A small cap, with rubber disc, through which the shaft passes, is fixed to the outer end of the sheath and prevents the escape of air from the urethra by this route. A tiny sleeve-like handle, fitted with a binding screw, can be slipped over the end of the shaft and fixed in any position, controlling the distance to which the instrument can be projected beyond the end of the cannula.

Method of Use.

The urethroscope and cannula with its contained operating instrument are used as one implement with one hand, the other hand, after projecting the operating instrument into the inflated urethra, being left free for other purposes. The operation is performed by moving the cannula in the urethra, and not by moving the stem of the instrument in its sheath, which it fits firmly. The cannula, therefore, must not engage the urethra too tightly.

Even when a filiform bougie or a long silver exploratory probe is used through the sheath it is usually better to push it well beyond the end of the cannula into the inflated urethra and to use it by manipulating the whole apparatus in the usual way. By this method it is easy to catheterise Cowper's ducts when the orifices can be made out. It will be noticed that as the cannula is made to serve the joint purposes of urethroscopy and instrumentation the light during the various movements will automatically follow the point of the instrument, and will at the same time be invariably directed to the spot that is being operated upon.

Owing to the mobility of the parts the oblique end of the cannula can be directed to any section of the urethral wall by tilting the urethroscope, and the least protrusion of the instrument beyond the end of the tube will bring it into relationship with the mucous membrane. An instrument must not be projected beyond the end of the cannula into the urethra until the latter has been inflated, and then only under direct control of the eye, and at the completion of the operation it must be withdrawn into the shelter of the cannula before the urethra has been emptied of air or the cannula removed.

Most instruments are designed to operate across the urethra. If, for instance, a knife in its sheath runs along the wall of the cannula, which is in contact with the floor of the urethra, the incision will take place on the roof of the canal. The snare, and the probe, when used for cauterising the lacuna, will, however, be placed and used on the same side as the lesion. Reference to the illustrations (A and B) will demonstrate this better than can be explained by words.

Therefore, see that the tubing from

Britain; excessive overcrowding in cities was due to unequal distribution of the population. The dissemination of the knowledge of methods of birth control dated from the time of the Bradlaugh and Besant trial in 1877.

Voluntary control might be divided into two classes, (1) criminal abortion; and (2) contraceptive methods. It was not, perhaps, quite correct in every case to use the word voluntary; the denial of the natural maternal instinct of women might be compulsory in so far as it was due to great economic and social pressure.

Criminal Abortion.

By criminal abortion was here understood all cases of artificial termination of pregnancy without the consent of the medical profession—i.e., fœticide or murder, no matter what justification might be given for its employment. It was increasing in this country and in America, was one of the prices we are paying for civilisation, and was widely used for the termination of legitimate as well as illegitimate conceptions; information of its employment was only obtained when the maternal victim had lost or was in danger of losing her life. Just punishment should be meted out to the couple who consented to the practice of abortion, as well as to the individual who procured it. There were two classes of criminal abortion from the medico-legal standpoint—those where the woman brought it about herself, and those where another individual performed the operation. In hospital practice women were constantly admitted suffering from hæmorrhage or sepsis, the result of self-induced abortion; the cause was perfectly apparent, but no action was taken beyond the giving of a moral lecture. In cases where abortion had been procured by another individual and where the patient came up for treatment of a condition which did not end fatally, was the medical attendant responsible for its notification, or must he wait until dangerous symptoms occurred and then be told in court that he was liable for imprisonment for concealing the facts from the onset of the fatal condition? It was difficult to estimate the prevalence of abortion. Until notification of all interrupted pregnancies was secured our knowledge of the loss of early ante-natal life was mere guess-work. Educate public opinion and provide facilities for adequate treatment and there would be little difficulty in estimating the prevalence of abortion.

Contraceptive Methods.

Knowledge of the use of contraceptive methods was now almost universal; books were sold broadcast in Britain, and meetings were held where sex problems were freely discussed; old-fashioned morality, like religion, was condemned as out-of-date. Societies competed in their efforts to spread information; the main arguments employed were that contraceptives formed a desirable alternative to criminal abortion, permitting of earlier marriages, and therefore diminishing venereal disease, illegitimacy, and prostitution, and the dangers of the unchecked propagation of the lower classes at the expense of the better and more prudent members of society. Malthus directed attention to the dangers of over-population and enjoined sexual abstinence as the remedy; the members of the Neo-Malthusian League supported his arguments but recommended contraceptive methods. The majority of supporters of birth control were perfectly genuine in their desire to solve the great social and economic problems of the day; but there must be danger in widespread and uncontrolled knowledge of sex matters and contraceptive methods. There must be some deep-rooted moral reason for the innate sense of modesty and reserve which only approached such subjects with reverence and which had for its purpose the preservation of the race. The traditional mystery of sex knowledge must have had some physiological basis to have withstood the length of ages. Was it not a sign of decadence that young men and women openly discuss before marriage the numbers of their future family, and when young women employ contraceptive mechanical or chemical methods as an immediate preparation for the marriage day? The medical profession were all agreed that a knowledge of sex hygiene is desirable, but it must to a certain extent be preceded by a moral and religious education. The young generation had gained much liberty, but might be losing the power of self-control. The future of the nation lay in the hands of women, properly educated, who realised what race suicide meant.

The Medical Aspect of Birth Control.

Limitation of the birth-rate should be for medical reasons only and should be considered from two points of view: (1) the possible danger of pregnancy to the individual; and (2) the undesirability of propagation of the unfit. Pregnancy might have to be prevented in the presence of some pathological condition, such as tuberculosis, toxæmia, venereal disease, or insanity, and in cases where too frequent pregnancies were undermining the health of the woman concerned. Propagation of the unfit might have to be prevented owing to the danger to the community of feeble-mindedness and increase of the criminal alcoholic classes. Surgical sterilisation for other than health reasons was absolutely to be condemned. There was no justification for the mutilation of an individual; moreover, the reproductive organs had a physiological influence upon metabolism apart from their specialised functions. The Jews condemned contraceptive measures and marriage of the unfit, with the result that their race persisted in spite of many difficulties.

It might be to the credit of the medical profession that it had hitherto avoided open discussion of such questions from a sense of morality and purity. But now the knowledge had been disseminated, and the profession must take up the question. If it is wrong to make use of contraceptive methods the profession should say so; if contraceptives are necessary, guidance should be given in their employment; they should then be sold by chemists of repute, and be obtainable on the order of any practitioner who advises their use.

The advocates of birth control quoted the approval of some of the members of the medical profession and medical journals. They spoke of the misery of the unwanted child and the worn-out mother, and at the same time they encouraged excessive sexual relationships among the married by depicting their delights and physiological necessities. How long were the medical profession to suffer the spread of such knowledge? Scientific and reliable methods must be discovered and kept under medical advice and control. Surely if the induction of abortion required the presence of two members of the profession for its justification the use of contraceptives should be controlled by similar ethical regulations. The methods employed were inseparable from the love of comfort and luxury which terminated the life of all civilised nations. They might be divided up into so-called physiological methods and the employment of chemical and mechanical appliances. Abstinence from sex relationship was possible in the unmarried state where the creative force was used in other directions, and where stimuli were avoided; it was easy for some individuals, difficult for others. In the married state it presented a different problem. Couples living in intimate affection were exposed to constant stimuli; ideals might be lived up to, but the resultant strain might be followed by evils worse than some contraceptive methods—namely, estrangement, unhappiness, infidelity, and divorce. Marriage was primarily for the controlled sexual relationships and the bearing of children. The church advised, in cases where abstinence was impossible, that sexual relationships should be restricted to the mid-menstrual period where fertilisation is at its lowest curve; but this was the period of least desire and had therefore an artificial aspect. Sexual relationships were matters of impulse and demanded satisfaction like hunger; the mutual desire of a married couple meant their happy balance. Intercourse when premeditated and when precautionary measures were taken was no longer a

Medical Societies.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THE annual general meeting of this Society was held at 11, Chandos-street on June 17th, the retiring President, Prof. W. J. R. SIMPSON, in the chair.

The PRESIDENT referred to the loss sustained in the death of Dr. A. J. Chalmers, in whose memory had been founded the Chalmers Memorial medal, as a biennial award for researches of outstanding merit contributing to the knowledge of tropical medicine or tropical hygiene.

Sir JAMES CANTLIE was unanimously elected President for the ensuing two years.

Snake-bite in India.

Major R. KNOWLES, I.M.S., read a paper on the Mechanism and Treatment of Snake-bite in India, based on work which had been carried out in conjunction with Major H. W. Acton, I.M.S., between the years 1912 and 1914 at the Pasteur Institute at Kasauli. He said that probably not more than two or three of the many species of vipers in India were fatal to man, and that even in untreated cases of true cobra bite the mortality could not be regarded as much over 40 per cent. Though the number of deaths in India from snake-bite was placed at 25,000 per annum, the cases of snake bite were likely to reach many more thousands. Hence the reputed efficacy of the many antidotal remedies which in reality failed to solve the problem of successfully neutralising a lethal dose of colubrine or viperine venom. Major Knowles described the grouping of poisonous snakes in India under three classes, types of which were represented on the screen: 1. The sea-snakes or *Hydrophinæ*, occurring in the salt marshes around the Indian coasts and at the mouth of the Shatt-el-Arab in the Persian Gulf, and characterised by their large size, fine heads, thin necks, thick bodies, and tails flattened like the blade of an oar. Little was known about their venom, but Sir Leonard Rogers had found it intensely toxic with marked paralytic action on the central nervous system. 2. Indian poisonous colubrines (the cobra, the king cobra or hamadryad, the kraits and coral snakes). The deadly nature of their venom rendered the treatment of snake-bite in India most difficult. 3. The vipers. Of this very common group in India, only two species, the Russell viper or daboia, and the *Echis carinata*, or saw-scaled viper, possessed enough venom of sufficient potency to be fatal to man, and although the small vipers frequently bit human beings, their bites very seldom, if ever, proved fatal.

The Study of Snake Venom.

The study of snake venom could be divided into four sections:—

1. *The estimation of the doses of venom usually injected.*—Experimental observations based on the hypodermic injection of 5 mgm. doses of desiccated cobra venom dissolved in normal saline into 465 rats showed that the rats died on an average 30 minutes after the injections. The minimum lethal dose (M.L.D.) of cobra venom proved by a series of further observations to be $\frac{1}{16}$th mgm. A rat did not die until one M.L.D. had been absorbed into the circulation. With massive injections of venom, the absorption period in the rat was just under 3 minutes, in the monkey it was 7 minutes, and in man probably not less, though not much more, than 10 minutes. It was ascertained experimentally that at a good bite the cobra parted with about two-thirds of the total venom content of its glands. Fresh cobras "milked" of every drop of venom had yielded a mean total of 317 mgm. of venom, two-thirds of which would be 211 mgm., or about 14 or 15 times the M.L.D. for a man. The observations resulting from experiments with the bitten rats showed that the dose of venom each received at a first bite varied between 3 and 360 mgm. of desiccated venom, a mean of 172 mgm. It was therefore concluded that the average dose injected would be somewhere between 211 and 172 mgm., although the actual figures showed extreme variation in the dose, and indeed one cobra had yielded a total of as much as 881 mgm., corresponding to 587 mgm. at one bite or 40 times the M.L.D. for man.

2. *Mechanism of the snake-bite.*—This marked variation was explained by consideration of the mechanism of the bite derived from dissection of the poison gland apparatus and musculature. Major Knowles described the anatomical parts concerned and the muscular action involved in the bite of the cobra showing that the mechanism was so complicated that the cobra might easily fail to yield a lethal dose of venom at a single bite, and where the amount of venom injected might vary from nil to as much as 587 mgm. The chances of escape were, indeed, so great that the mortality, even in untreated case of cobra bite, could not be put higher than 40 or 50 per cent. Major Knowles also gave an account of the bite and nature of attack of the vipers which differed in many respects from that of the cobras.

3. *Toxic properties and composition of snake venoms.*—Not only did the mechanisms of the bites of colubrine and viperine snakes differ, but also the poisonous action of the two classes of venom. Each contained three toxic elements. The colubrine venom included: (i.) a hæmolysin, dissolving the red corpuscles; (ii.) a cardiac stimulant; and (iii.) a neurotoxin capable of paralysing the central nervous system and causing death by its action on the respiratory centre. In man death occurred from asphyxia in 30 minutes to 30 hours from the bite. The viperine venom contained: (i.) a hæmolysin; (ii.) a coagulin, causing blood coagulation and occasionally fatal gangrene, or, in the case of small animals, sudden death by pulmonary embolism from lodgment of a detached clot; (iii.) a cytolysin or endolysin, causing destruction of the fine endothelial lining of capillaries and venules all over the body, which resulted in bleeding from all mucous membranes with both internal and external hæmorrhages, and after the onset of sepsis ended in death from cardiac failure. The fatal issue from cardiac failure might therefore, in the case of a viper bite, be due to a variety of causes and occur in from two to seven days. Major Knowles referred to the fact that the venom being a modified saliva, in addition to its lethal action, it played an important part in digestion. This accounted for the snake's habit of salivating the entire body of its prey previous to deglutition.

Experiments had been carried out to ascertain the effect of heat on venom solutions and to test the toxicity of the heated venoms. It was found that the proteids of cobra venom coagulated at 65°C. and the hæmolysin was destroyed at 80°C., although at that temperature the venom still retained 80 per cent. of its toxicity. The viperine venoms, on the other hand, proved less thermostabile and on heating lost their toxicity more rapidly, and the cytolysin was destroyed at 85°C. Chemical analysis had shown that the toxic principles of snake venoms were of complicated composition, comprising a range of proteids and non-coagulable proteoses. Major Knowles then classified the various poisonous snakes of India according to the toxicity of their venom.

4. *Treatment of snake-bite.*—Major Knowles gave the following conclusions as to the value of physical measures: (1) Excluding amputation or excision of the bitten part which to save life must be immediate and not delayed beyond a quarter of an hour, all physical measures were but supplementary to other forms of treatment. (2) Ligature of the limb after cobra bite merely locked up the venom, which flooded the circulation as soon as the obstruction was released, and eventually killed the patient. In the case of viper bites, however, ligature might save life, as the venom by giving rise to local thrombosis was not absorbed into the general circulation,

medical profession, for no one knew anything about it. With regard to Earl Russell's question as to cannon-fodder, she considered that the happiness of the entire world depended on the supremacy of the white races. She recognised the difficulty of the economic burden, but had not had space to include its consideration in her paper. It was obvious that many people would rather give one child a good education than be forced to have several children educated in a less complete way, but there were now schemes of insurance by which this difficulty might be overcome. With reference to the methods of contraception, she had no personal experience of the harmful results of quinine. The use of a cap placed over the cervix was most harmful; this means was advocated by up-to-date supporters of birth control, but the cap did not always remain in place, and when it did the discharge from the cervical glands was retained. There was no proof that the spermal fluid was absorbed by the vaginal glands; the existence of those glands was not yet certain, and in her opinion absorption took place through the cervix.

In conclusion, Prof. McIlroy described the contrast between the healthy and prolific lives of the Slav peasants in Serbia and Bulgaria with the decadence of the upper and middle-class Russians whom she had met in great numbers as refugees at Constantinople. The latter had committed race suicide and were dispossessed by the cleaner-living peasantry of their country. Sex instinct was created for one purpose only, and must have some outlet if its normal activity is interfered with. Continence in marriage would certainly be assisted by separate bedrooms and other housing facilities. In India, a country of prolific and moral people, the women were dressed properly and kept out of the public view; whatever we might call the Turk, he was one of the most moral of men in his sexual relations. Modesty must be retained for race preservation. As regards the right of the medical profession to interfere with the lives of married people, the supporters of the use of contraceptives had already interfered; the medical profession had been backward in its reply. The whole question must be brought into the open air and put on a proper basis.

MIDLAND TUBERCULOSIS OFFICERS.

Formation of a Sub-group of the Society of M.O.H.

A MEETING of Midland tuberculosis and assistant tuberculosis officers, convened by Dr. A. Ashkenny, tuberculosis officer, West Bromwich, was held in Birmingham on July 9th. Dr. G. B. Dixon, tuberculosis officer, Birmingham, was elected to the chair. After the chairman explained the object of the meeting the following resolution was adopted unanimously:—

> That this meeting of Midland tuberculosis officers and others interested in tuberculosis approve, and hereby resolve to form themselves into, a Midland Tuberculosis Sub-group of the Tuberculosis Group of the Society of Medical Officers of Health.

The chairman was elected temporary president and it was further resolved:—

> That a temporary committee of five members be formed of those employed exclusively in clinical tuberculosis work to assist the President until the next meeting of the sub-group in October.

The following members were elected to this committee: Dr. T. R. E. Elliott, Dr. A. G. Campbell, Dr. J. A. M. Clark, Dr. D. J. Peebles, Dr. H. Gordon-Smith. The following were coöpted to assist the committee and president: Dr. N. A. Coward and Dr. Edwards.

CONTROL OF MEASLES IN LONDON.—The recommendations of the Public Health Committee of the London County Council, which appeared in THE LANCET last week, were adopted by the Council without further debate. The Council will now consult the metropolitan borough councils regarding the issue of a circular to medical practitioners in London, directing attention to the facilities available through the public health services for the nursing of cases of measles in London. Representations will also be made to the Minister of Health, that in the opinion of the Council it would not be desirable to adopt the proposal to make measles compulsorily notifiable by medical practitioners throughout London.

Reviews and Notices of Books.

SYPHILIS.

Syphilis and its Treatment, with Especial Reference to Syphilis of the Skin. By WILFRED S. FOX, M.A., M.D., B.C.Cantab., M.R.C.P.Lond. London: H. K. Lewis and Co., Ltd. 1921. Pp. viii.+195. 36s.

Dr. Fox is happy in the material which he has selected to place before the reader and in the manner in which he has presented it. The emphasis on the dermatological aspects of syphilis implied in the title may help to foster a sense of proportion in respect to the diagnosis and treatment of syphilis which is in some respects lacking at the present day. When a medical man who does not possess a sound knowledge of dermatology undertakes the entire charge of a patient suffering from syphilis he is assuming dangerous responsibility, while extension of the purely empirical treatment of syphilis is deplorable. Attendance at a venereal clinic for a short time may render a practitioner sufficiently adept in the administration of intravenous medications, but it should also teach him how hard it is to become proficient in the treatment of syphilis. By the attention which Dr. Fox has devoted to the dermatological aspects of the disease he has rendered great service to the profession.

In the earlier part of the volume he deals adequately with the differential diagnosis of chancres, and figures of the various lesions of the same level of excellence in the numerous other illustrations would have been helpful. With Chapter IV. Dr. Fox enters upon an account of the secondary period. After giving a general description of the secondary cutaneous lesions he turns to the general pathogenesis of cutaneous syphilides, of which he writes admirably. Dealing with the confusing subject of secondary rashes he is certainly happy in his method of classification and description. He adopts a classification of secondary rashes based upon "the dermatological elements they exhibit," which is undoubtedly a more scientific method than that founded upon the chronological order of their appearance. A knowledge of the anatomy and physiology of the skin is assumed for the reader, and might perhaps have been added. The medical student learns little about the skin during his anatomical and physiological career, and during his hospital life, though he may see many of the lesions affecting this structure, the gap is seldom filled. Perhaps in the next edition Dr. Fox will consider this point worth his attention. Chapter VII. is devoted to a consideration of "the Wassermann Reaction," and the author utters a warning note against the empirical reliance upon the results of the test. The course to be adopted when patients with an old history of syphilis present themselves for medical examination, after a long period of uninterrupted good health without treatment, requires close consideration. When clinical investigation reveals neither signs nor symptoms, should such persons be subjected to the Wassermann test? It may easily be positive, and though the patient might have lived for the remainder of his days without exhibiting any lesions attributable to the original attack, his life is rendered one of continuous terror. The "tyranny of the Wassermann reaction" is upon him. The practitioner need never hesitate to seek special guidance when confronted with such a problem.

Another subject upon which we need information is the data on which to base an opinion as to when a patient may be allowed to marry. What are the fundamental principles which must guide to so momentous a verdict? Much may be deduced here from a careful study of Dr. Fox's work.

We recommend this work to all who deal or intend to deal with syphilis.

in blood pressure, and subsequent injection of viperine venoms produced no further dilatation of the blood vessels, and, vice versa, there was evidence of vasomotor paralysis produced by these venoms, including those of the African puff-adder, whereas the rattlesnake caused no clotting but only vasomotor paralysis. He mentioned adrenalin and pituitary extract as having a marked effect in averting vasomotor paralysis following a small dose of venom. The use of antivenene for bites of viperine snakes as employed by Lamb was important to counteract vasomotor paralysis. Antivenene against cobra bites was also active to a less extent against the venom of the *Hydrophineæ* or sea snakes. Local antidotal treatment, by means of Lauder Brunton's snake lancet and permanganate cauterising, should be immediately followed by injection of antivenene if available. He had recorded recovery in 10 out of 12 cases of snake-bite with the use of potassium permanganate and incision, and he recalled that gold chloride was found by D. D. Cunningham to be more effective than any other drug; but time was the essential factor in the treatment of snake-bite, as cases must be seen very early to give much chance of success.

Dr. **Ernest Black** stated that he had conducted experiments with snake venoms 20 years ago. There was then the widespread but mistaken view that antivenene should be used universally, whatever the snake might be. But it had since been definitely established that antivenene was not specific except for the actual species of snake venom from which it had been prepared. Its use against other snake-bites might indeed accelerate death.

Major **H. C. Brown**, I.M.S. (retired), described briefly the process of immunisation of the horse to snake venoms and drew attention to the difficulties connected with it, chiefly owing to abscess formation. He suggested that the valuable work of Major Knowles and Major Acton on the concentration of antivenene might obviate this difficulty by keeping the horse on small doses of venom and subsequently concentrating the antivenene. He said that he had had experience in controlling hæmorrhages such as epistaxis by the administration of normal horse serum, and suggested that this serum might be of value in the hæmorrhages due to viperine bites; he had treated one case of *Echis carinata* bite, showing extensive hæmorrhages, with normal horse serum with apparently much benefit to the patient. He asked Major Knowles whether he had had any experience in the use of normal horse serum or of non-specific antivenenes in cases of hæmorrhages due to viperine bites.

Major **Knowles** in replying stated that the use of permanganate crystals following incision into the wound was not to be compared in value with that of injection of the salt in solution into the site of the snake-bite, as the latter method had much better chance of reaching and destroying the venom. He regarded the beneficial effect of horse serum in arresting hæmorrhage as being due to hæmostatic action, but he had no experience of its use in the treatment of hæmorrhages due to viperine bites.

Sir **James Cantlie**, concluding the discussion, said that he had seen Calmette's work at Saigon 20 years ago and he now realised that much of what he had learnt then was incorrect as regarded the dosage of antivenene. He gave reminiscences of cases of snake-bite in China and recalled the native method of treatment, then in vogue, of applying a tourniquet above the bite for long periods, as the result of which the wounds remained unhealed for several months.

UNIVERSITY COLLEGE, LONDON.—The following awards in the Faculty of Medical Sciences have been made at University College: Cluff Memorial Prize: Katharine A. C. Gillie. Anatomy—Senior Class Gold Medal: L. Reuvid; Junior Class Silver Medal: Mary E. Tyars. Physiology—Senior Class Gold Medal: Katharine A. C. Gillie; Junior Class Silver Medal: Iris M. Harmer. Organic and Applied Chemistry—General Course Silver Medal: Marian G. Palmer.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held on July 7th at 11, Chandos-street, Cavendish-square, W., the President, Lord Justice **Atkin**, being in the chair. A paper was read by Prof. **A. Louise McIlroy** on

Some Factors in the Control of the Birth-rate.

Prof. **McIlroy** said that a nation was maintained in power according to the endurance, strength, and fertility of its members; if the individual could not contend against destructive forces it must have increased fertility to compensate for the consequent mortality. When a high degree of civilisation gives capacity for self-preservation fertility is low; of animals which reproduce by spawning a large number are lost; in contrast with this type is the comparatively small multiplication of the human race. In the latter, moreover, there is low fertility in the better educated classes and high fertility in the lower or submerged classes. In Britain the birth-rate increased rapidly in the industrial period of the nineteenth century, when there was great commercial expansion and demand for both adult and child labour. Large food-supply areas were opened up and methods for the lowering of the death-rate were considered; but during the past 40 years the birth-rate in England fell steadily until it is about one-third of that of 1860; also, during the war, the best stock was sacrificed to save the Empire from destruction. The low birth-rate in France had very serious consequences for that country in 1870; to it may be attributed Germany's opportunity in 1914. The birth-rate was high in Eastern Europe, especially among the prolific but short-lived Slav races; thus Russia had always been a menace to the great Saxon and Teutonic nations.

Had the decline in the birth-rate in Britain any political significance, or was it merely nature's method of keeping an expanding population in check? The evidence given before the Birth-rate Commission went to prove that although the decline is due in part to economic and trade conditions, it mainly owes its low rate to the artificial control of conception. The normal checks by which a country's population is kept within economic limits were the death-rate and the restrictions upon fertility; the death-rate was maintained by age, disease, war, dangerous occupations and environment, and fertility was restricted by civilisation, the limited reproductive life of a woman, delayed marriage, abortions, &c. Other factors which influenced the death-rate were fœtal and infantile diseases, infanticide, illegitimacy, alcoholism, venereal diseases, and prostitution. The arguments in favour of a low birth-rate were individualistic; a small population left more room and gave better social conditions, more demand for labour, and higher wages. In China, where there is a high birth-rate and where the population might be said to have reached the point of saturation, there was a high death-rate, especially marked among infants, few means being taken for their preservation.

The arguments for a lowering of the birth-rate were put forward in justification of the ideal that a small number of useful well-cared-for healthy citizens are more beneficial to a State than a large number of unfit; there would be no danger to the British Empire if other nations also controlled their populations, but it must be remembered that Germany was not beaten, and would encourage any influences which would tend to diminish the fighting resistance of Britain and France. In the East, where reproduction is encouraged to its utmost limits, Japan and China might yet form a danger to the white races. Was the supremacy of the British Empire to be maintained over the native races in the face of a rapid fall in the birth-rate both at home and in our colonies? Such a fall had been the end of many of the great nations in history. The dangerous aspect of the question of birth control should not be ignored by the State; there was no evidence of excess of population in by Dr. M. L. Babonneix. This section contains some excellent plates illustrating the pathology of tabes. The diagnosis and pathology of nervous syphilis claim the greater part of the section, the shortness of the paragraphs on treatment serving to emphasise the intractable nature of tabes and general paralysis. The work is illustrated but not lavishly. The volume is remarkably complete, but in a work of reference we should have welcomed the inclusion of a bibliography.

THE OCTOCENTENARY OF READING ABBEY, A.D. 1121–1921.

By JAMIESON B. HURRY, M.A., M.D. London: Elliot Stock. 1921. Pp. 92. 10*s.* 6*d.*

Dr. Hurry is well known as a writer on archæology, and especially on the history of Reading Abbey. Most of his books are now out of print, and therefore, as he tells us in his preface, he has collected some scattered papers and bound them up in the volume before us as an eight hundredth "years mind" (to use the old technical expression) of the great Benedictine house at Reading. The volume is confessedly slight and sketchy, but there is more information in it than would at first appear from the size of the book, and we are glad to say there is an excellent index. Dr. Hurry gives particulars of the founder, Henry I., of the foundation itself, and of the daily round in a religious house. On p. 33 there is a statement which has somewhat puzzling features: "After chapter came the chapter Mass, followed by study or exercise, till the bell summoned to the office of Tierce; this in its turn was succeeded by the principal act of the day, the sacrifice of the Mass." In any religious house, whether monastic, collegiate, or a cathedral establishment, the principal service of the day is the chapter Mass, otherwise called capitular, or solemn, or conventual, or stational, or principal, or greater Mass. But the word Mass was anciently used to describe any office of simple praise and prayer which was concluded by the bishop with a *collectio*, or summing-up prayer, and possibly Dr. Hurry, when he refers to the Chapter Mass, means the office with which the chapter concluded. If he means the capitular Mass, the "principal act of the day" would not have followed, for the capitular Mass *is* the principal event.

We are quite at one with Dr. Hurry in his protest against the manner in which the monastic buildings and establishments were treated at the dissolution; he points out rightly that Reading Abbey Church might have been made a cathedral for the county of Berkshire, and the other buildings retained as a hospital or almshouse. The granting of the Church's lands and moneys to greedy courtiers, such as Somerset, who pulled down much of Old St. Paul's to build Somerset House and tried to pull down Westminster Abbey for the same purpose, or that wretched creature, Sir Richard Rich, to whom was granted St. Bartholomew the Great, was one of the worst features of the Reformation. It is true that the religious houses had in many cases fallen from their first estate—there could hardly be a more severe indictment than Cardinal Morton's of St. Alban's Abbey in 1489—but Cromwell and Henry VIII. had but one idea of reformation, and that was robbery accompanied by injustice. Here is Cromwell's note on the "trial" of the last Abbot of Reading: "The Abbot Redyng to be sent down to be tried and executed at Redyng with his complices."

Dr. Hurry's book contains some good illustrations, reproduced mainly from a series in the municipal Art Gallery. Plate IV. is a picture by Mr. Stephen Read, representing the Consecration of the Abbey Church by Thomas à Becket. Mr. Read's imaginary presentment of Becket represents a dreamy and delicate girl, totally unlike what that masterful personage must have been, though we believe that previous presentations have been similar in character; for an imaginary portrait of Becket we much prefer Tenniel's, as given in The Brothers of Birchington, to all readers of "The Ingoldsby Legends."

CHEMISTRY.

Dairy Chemistry. A Practical Handbook for Dairy Chemists. Third Edition. By H. D. RICHMOND. London: Charles Griffin and Co. 1920. Pp. 490. 25*s.*

THIS well-known standard work was written for dairy chemists and others having the control of dairies. The fact that it has been necessary to prepare a third edition since 1915 is sufficient testimony to its value. It is a natural and healthy indication that a voluminous and ever-increasing literature centres around one of the staple foods of mankind, and Mr. Richmond's brother chemists should be grateful that he has found time not only to bring this book up to date, but to effect considerable improvements in the treatment of the several subjects dealt with. His book, which contains a number of useful illustrations, is now divided into three parts: the constituents of milk, the analysis of milk and milk products, and technical applications. That portion dealing with biological and sanitary matters will appeal to the medical officer. The writing is good and there appear to be very few mistakes. One small point which Mr. Richmond might consider in the next edition is the substitution of clear and well-defined illustrations for those which are blurred.

Aids to Chemistry. By WILLIAM PARTRIDGE, F.I.C. London: Baillière, Tindall and Cox. 1921. Pp. 280. 6*s.*

THIS little book is intended for medical, veterinary, dental, and pharmaceutical students who have passed through a course of chemistry. One-fifth of the space is devoted to general considerations of chemistry, and the subjects dealt with include non-metallic elements, the commoner metals, carbon compounds, aliphatic compounds, cyanogen compounds, aromatic compounds, and heterocyclic compounds. The matter is judiciously selected, free from errors, and arranged in a convenient manner. Those who like to have their information in "tabloid" form will, no doubt, approve of Mr. Partridge's effort.

BOTANY

A Text-book of Botany for Medical and Pharmaceutical Students. By JAMES SMALL, D.Sc. Lond., Ph.C., F.L.S. London: J. and A. Churchill. 1921. With 1350 illustrations. Pp. x. + 681. 25*s.*

THIS text-book of Botany provides reading sufficient to cover the work required for the examinations (qualifying and major) of the Pharmaceutical Society and also for the botanical syllabus of the medical curriculum. The volume carries us even beyond these limits, giving a careful reader an all-round acquaintance with botanical science, approximating to the requirements for a pass B.Sc. degree.

The subject is developed in a way that makes the book rather difficult reading for a beginner. After an introductory chapter describing briefly the life-history of a dandelion, seeds are discussed and the germination of typical examples is described. Then follows a chapter upon the cell, including all the intricate details of nuclear structure and division. Chapters on the morphology and anatomy of stem, root, and leaf follow in succession, Plant physiology occupies the next four chapters; then buds, phyllotaxis, the flower, pollination, fruits and seed dispersal. Permeability of the protoplasm, plant movements and ecology fill the closing chapters of Part I.

Part II. is concerned with classification and includes a description of all the great groups of plants beginning with the Algæ and proceeding to the Angiosperms. Types of these groups are not considered separately in detail, but examples are used to illustrate the general vegetative and structural features of the group as a whole, and the physiological peculiarities. Methods of sexual reproduction are next considered, followed by asexual reproduction, vegetative propagation, and classification. The method of treatment adopted by spontaneous act; and the other artificial methods of birth control, were, as a rule, unreliable and offended the æsthetic sense; they led to local pathological conditions and to general neuroses. Their advocates had not unlimited faith in mechanical methods, as in most cases they advise their combination with chemical substances such as quinine.

Discussion.

Dr. **AMAND ROUTH** said that the expression "birth control" was misleading in a special sense; "conception control" was a better term for the methods of contraception under discussion. The smaller families of the present day resulted from knowledge of conception control, and every method in use was harmful to the nervous systems of those employing it; *coitus interruptus*, the method most common amongst the poor, was the most harmful of all. No means of conception control, save that of abstention from intercourse, should be used except upon medical advice. It was perfectly easy for a married couple to have a child every two years; taking into account the periods of pregnancy and lactation, for neither sex would the necessary self-control be too difficult.

The speaker then read statistics relating to the high rates of ante-natal, intra-natal, and neo-natal mortality in the British Isles, dealing in turn with prematurity, difficult labour, toxæmia, syphilis, and the significant heading "unknown causes." The facts of latent syphilis during pregnancy, he said, had recently been discovered, giving the explanation of the birth to infected parents of non-infected children; the spirochæte could be broken up into granules and rendered harmless by defensive chemical action taking place in the placenta. If every pregnant woman came under proper treatment congenital syphilis could be obliterated. The difficult position of a doctor in a case of induced abortion had been considered some time ago by the Royal College of Physicians of London, who passed resolutions to the effect that (1) a moral obligation rests upon every medical practitioner to respect the confidence of a patient, and (2) every medical man should urge his patient, particularly if there was likelihood of the latter's death, to make a statement as to the performance of the operation.

Earl **RUSSELL** wished to know the ideal behind the encouragement of an unchecked increase of population. Some people felt that it was advocated by those whose only concern was the supply of cannon-fodder for the armies. For himself the size of the British Empire mattered little; what mattered was the happiness and intellectual progress of its people. According to Prof. McIlroy and Dr. Routh the parents had apparently little to do with the matter; but medical measures of control would have to be of a nature acceptable to the laity, and many of the laity were not in an economic position to raise families except with State aid for mother and child. He totally disagreed with the idea that it was shocking for engaged couples to discuss fully the matter of children; such discussion marked a great improvement on Victorian ideas, and showed forethought not to be deprecated in the building-up of the nation. If it were true that all contraceptives were harmful, it was the duty of the medical profession to make the facts known to all. From the Parliamentary and legislative point of view, if the sale of contraceptives was made illegal, as urged by the Bishop of London, it would lead to much more serious evils, including a great increase in criminal abortion.

Dr. H. G. **SUTHERLAND** said that the economic side of the question of birth control was raised in the interest of the poor; but it was not the poor who failed in their duty—it was the well-to-do, whose motive was not economic difficulty, but selfishness.

Dr. **BERNARD O'CONNOR** considered that there was no logical difference between germicide and infanticide. The medical profession must set its face against immorality.

Dr. **HADEN GUEST** believed there was no definite solution to the very complicated sexual problem. Control of the sexual impulse was, as Prof. McIlroy had said, very necessary; but in England control was understood to mean repression. Life was happier in the Latin countries because there means were found for freer sexual expression. In India, where unfaithfulness in marriage was rare, the young people were highly trained to make love; they were taught to express themselves, not to bottle up the impulse in the manner of the Anglo-Saxon and Teutonic peoples. Sexual impulse could be trained and refined, but not repressed. Many of the methods of contraception were harmful; others, so far as he knew, were not; and what harm they might do must be counterbalanced by the harm resulting from repression. Under the present economic conditions, and in the present age of badly-adjusted nervous mechanism, few people could successfully raise a family of children born at the rate of one every two years.

Mr. **BERNARD SHAW** said that he viewed the subject without prejudice; the view of the Catholic clergy might be described as superstitious, but priests were men accustomed for long years to give good domestic advice. A priest would laugh at the idea that a life of complete abstinence in this respect was impossible; comparison of the voices of the men who sang in Westminster Cathedral with those of some who sang in music halls would suggest that such a life brought certain compensations. But he gathered that neither priest nor doctor really knew anything about the subject. As regards the view of the population as people who would fight, only 11 per cent. of British subjects were white, and only 35 per cent. of the people of the French Republic; both these countries could put enormous armies of black, brown, and yellow men into the field in time of war, and birth control amongst the whites might mean their swallowing up by those of other colours. He favoured birth control for the sake of control, which was desirable for its own sake in all human activity, and marked a step forward in civilisation and development. With reference to methods of control, he agreed largely with Dr. Guest; the harmfulness of these methods varied largely with the individual. Housing and diet had much to do with the provision of frequent stimuli. Parents naturally considered the question of expense. If women were really intelligent they would refuse to bear children unless they were well paid by the State for so doing. The income-tax form was, however, a beginning in this connexion. The reader of the paper had spoken of natural modesty, but in his opinion a great deal of modesty was not natural, but violently inculcated. The revolt against conventional modesty had resulted in immodesty. He wanted to appeal to the medical profession not to put forward claims to interfere in the private lives of married people.

Lord Justice **ATKIN**, in summing up the discussion, described as paradoxical the endowment of motherhood as a suggested cure for recourse to contraception; the necessary taxation might become so heavy that compulsory contraception would also become necessary. His experience in the criminal courts had shown him the misery caused by the professional abortionist. From all points of view birth control was a matter of the gravest importance in social and family life; married people owed a duty to the State, the stability of which rested upon the way in which children were born and bred; the use of contraceptives was undesirable because it favoured the avoidance of marriage and of the birth of children after marriage. It might come to a question of reasonable use of contraceptives; their total abolition was a counsel of perfection. The knowledge concerning them could not now be eradicated. The medical profession should make known statistics dealing with the effect of their use upon health rather than interfering with the tide of knowledge already abroad. The society was greatly indebted to Prof. McIlroy for her brave and open treatment of the subject.

Prof. **McILROY**, replying, said that the discussion had shown her that no guidance was to be had in the matter. The whole question must be taken up by the equivalent of the calcium attached to it. Calcium, combined with an organic substance at present not defined, is the essential factor in the commencement of blood coagulation; this complex probably corresponds to the thrombokinase of Morawitz.

The Oxygen Use of Muscle and the Effect of Sympathetic Nerves on it, by Hiromu Nakamura. The author's results refer to the rate of blood flow and oxygen exchange in the muscles and bones of the lower leg of the cat. The rate of flow makes no difference to the rate of oxygen use, except when the flow becomes very small. Section of the sciatic nerve when the sympathetic is intact causes in anæsthetised animals, in harmony with the experiments of others, an increase in rate of blood flow. Such section does not cause decrease in oxygen use. Stimulation of the peripheral end of the lumbar sympathetic causes great decrease both in the rate of blood flow and in oxygen use; the latter is probably a consequence of the former. The author concludes that the sympathetic does not increase the oxygen use of muscles, and, in agreement with Frank and Voit (1901), that the ordinary (extensor) muscular tone kept up by somatic nerves does not increase oxygen use. The rate of blood flow and oxygen use, both in anæsthetised and in decerebrate-curarised animals, was found to be unaffected by section of the sympathetic nerves, and by section of the sciatic after the sympathetic nerves have been cut.

Effects on the Frog's Heart of Varying the Alkalinity and Calcium Content of the Perfusing Fluid, by W. Burridge. In perfusion experiments on the frog's heart the effect of alkali depends, within certain limits, on the amount of calcium. Similarly the effect of calcium depends on the amount of alkali.

The Regulation of the Water Content of the Human Organism, by Edward F. Adolph. The experiments were undertaken to define some of the conditions which determine the amount of water in the body, and to exhibit the normal adjustments of the body fluids; they were therefore made by introducing water and other substances into the circulation from the alimentary tract, and not by intravenous injections, as these present very unusual and drastic conditions to organs of regulation—particularly to the kidneys—or by curtailment of their introduction. The addition to the body of water alone, accompanied by salts or urea, is not permanent. The solution retained for the greatest length of time is 1 per cent. sodium chloride. Water may be abstracted from the body by a large variety of methods, several of which were studied comparatively—e.g., use of nutrients having small water content, chiefly meat, bread, butter, jam, cake, and sugar, with sweating and thirsting. When no other constituent has been abstracted meanwhile, the body-weight is completely restored by drinking water. Depletion in water does not inhibit process of growth. The excretion of water, chloride, and urea during a diuresis due to any one of them is by far the most accurate indication so far studied as to whether the water of the body is normal in quantity. The water content of the whole organism is independent of every other single substance. The content may be raised by introducing a temporary store of salt or carbohydrate; this water is not a part of the essential structure of the body. Other than this, no evidence has been found for a reserve of "free" water; in thirst the excretion of water is kept up at the expense of water from the tissues themselves.

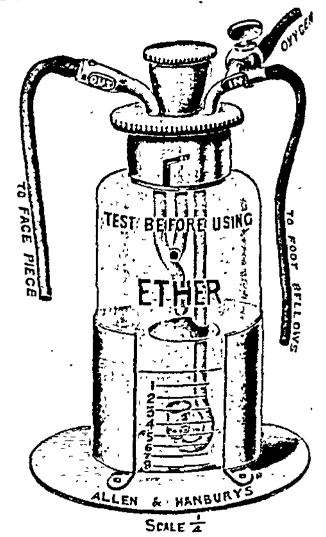
The Regulation of the Supply of Energy in Muscular Contraction, by W. Hartree and A. V. Hill. The following are a few of the conclusions arrived at by the authors. A single maximal shock produces considerably more heat at a lower temperature: a tetanic stimulus of about 0·017 second duration produces practically the same heat at all temperatures. A longer stimulus produces far more heat at a higher temperature. In a contraction the heat produced is the sum of two factors, corresponding to the two functions of a muscle of maintaining a force and of doing work. Interesting details as to the heat produced per gramme of muscle per second of stimulus, per cm. length of muscle per gramme weight of tension maintained per second of stimulus, and of the "efficiency" of muscle and other results, for which reference must be made to the paper itself.

New Inventions.

AN IMPROVED ETHER INHALER.

THE old Junker inhaler, holding an ounce, or at most two ounces, of chloroform, was a satisfactory inhaler in the days before the objection to chloroform was recognised. Ether, however, which demands a 15 per cent. vapour, needs an apparatus correspondingly larger in size. The essential requirements of such an apparatus are that is should be not only simple and portable but perfectly safe. These essentials have been very satisfactorily combined in the apparatus which I here describe.

It consists of a strong glass jar with nickelled metal cap, carrying inlet and outlet tubes with a funnel between them for the introduction of fluid ether. It is graduated to one-third of its height to hold eight ounces of ether. The inlet is bifurcated, one branch for oxygen if required, the other for connexion to a simple hand bellows or to a foot bellows. The outlet tube carries a three-foot rubber tube for attachment to a face mask, or to a mouth tube, or gag. The danger of faulty adjustment and the blowing over of fluid ether has been fully met and countered by the use of two ball valves. They admit the passage of vapour in one direction only and faulty adjustment is at once apparent, for in this case the instrument would not work. The large splasher situated below the out-going tube effectually prevents any entrance of fluid ether. Again, the impossibility of fluid ether passing over is secured by the central position of the vapour outlet above the splasher, for in whatever position the bottle may be placed, upon its side or upside down, no fluid ether can possibly pass over. The apparatus is simple, safe, and even "fool-proof."



SCALE $\frac{1}{2}$

The chilling of ether fluid by the passage of air through it may be avoided by placing the bottle in an ordinary enamelled jug, one-third filled with hot water, or by using a leaden coil immersed in boiling water, placed between the air bellows and the ether bottle.

I have fully tested this apparatus and believe it will be found perfectly satisfactory. It should appeal to many who do not take kindly to the transport and haulage of the more complicated and ponderous plants of anæsthetic machinery. The apparatus has been made for me by Messrs. Allen and Hanburys, Ltd., Wigmore-street, W.

Hampstead. L.R.C.P. Lond.

Mr. Samuel Osborn, M.R.C.S. Eng., has received the King's permission to wear the Cross of Chevalier of the Order of the Crown, conferred upon him by the King of the Belgians in recognition of services to the Belgian sick and wounded in the late war.

Atlas de Syphilimétrie. Les conditions expérimentales de l'extinction de la syphilis. By Dr. ARTHUR VERNES. Paris: Libraire Félix Alcan. 1921. Pp. 121. Fr.35.

IN his "Atlas of Syphilimetry" Dr. Vernes strikes out a new line in the control and treatment of syphilis. He first establishes his diagnosis, not only whether syphilis or not, but the *degree* of syphilis; then he carries out his line of treatment; and finally puts every case to a supreme test, which he calls the "law of the three eights." He states that out of 20,000 cases no patient who has satisfied this law has ever been found to show any further sign of syphilis, nor has the offspring of any such patient shown any hereditary taint of the disease. His book is divided into five parts under the following headings: I. The Principles of Syphilimetry. II. The Law of the Three Eights. III. Arsenical Treatment. IV. Centres of Resistance and Mercury. V. Syphilitic Infection and Syphilimetry.

According to Dr. Vernes syphilis provokes a definite change in the blood serum. On adding to any human serum a substance which he calls péréthynol (a fluid containing an infinite number of ultra-microscopic granules in suspension) there occurs "flocculation"—that is, the granules congregate into masses, microscopic at first, later more and more visible. Péréthynol is prepared by extracting horse's heart with ethylene perchloride and alcohol, the details of the procedure being very elaborate. In syphilis this phenomenon of "flocculation" is much more marked in proportion to the intensity of the infection. If pig's serum is introduced into a suspension in process of "flocculation" the collections of granules disappear. On the other hand, pig serum is hæmolytic for sheep's red corpuscles. Dr. Vernes adds together péréthynol, human serum, pig serum, and, later, sheep's cells, and finds that the hæmolysing power of the pig serum varies inversely with what he calls its property of preventing flocculation, so that the degree of hæmolysis may be taken to correspond to the intensity of the syphilis, being complete with a normal serum and nil with a powerful syphilitic one. The degree of hæmolysis is compared with an artificially prepared scale of tints: T 0, T 1, T 2, T 3 . . . . T 8. (T 0 = no hæmolysis; T 8 = total hæmolysis); and in this way Dr. Vernes claims to be able to measure the intensity of the infection and to plot it as a curve.

The "law of the three eights" depends on the observation that normal serum always gives tint 8, corresponding to complete hæmolysis in the colorimetric scale. With the development of syphilis the curve rises from 8 to 0. The action of arsenical treatment shows itself by a gradual fall, which may be transitory or permanent. A return to tint 8 is considered permanent when the patient has satisfied the test of the *three eights*—tint 8 on examination once in each of eight months commencing from the last arsenical injection, and tint 8 with the cerebrospinal fluid at the end of this period.

Dr. Vernes claims that he has not seen this law broken, in spite of strict control for ten years. The patient who has fulfilled this test can contract syphilis anew, and infants born under its protection have never, according to him, shown any signs of syphilis, clinical or serological. He makes a great point of the rhythm of treatment and insists that it is much more important than the total dosage. He believes that the only permanently resistant form of syphilis is G.P.I., and says: "In any suspected case of this latter, successful treatment invalidates the diagnosis." He also contends that "the essential character of intervention to be effective is *intensity*."

Dr. Vernes is to be congratulated on the production of a lucid and interesting atlas. The excellent charts are in no way cramped and are, for the most part, to be found close to those parts of the text to which they refer, thus saving the reader the trouble of hunting for them. The author makes many bold statements, and claims, even to dogmatism, and he will find a number of people who do not agree with him. For example, he attempts to criticise and discredit the Wassermann reaction by saying that it is not a true application of the Bordet-Gengou phenomenon. His own experience is founded on a very large series of cases, and if only half of what he claims be true, his methods would warrant an exhaustive trial. We could have wished for some further explanation of how the author fixes his courses of treatment and the amounts of individual doses and their spacing; in some cases a dose is smaller in amount than the preceding or succeeding one, even when no blood examination has been done in the interval. Nor are we told what proportion of all cases or of each kind in the author's series has satisfied the "law of the three eights." The methods set forth demand considerable skill and experience and a perfectly fitted laboratory, but what man, who has any real knowledge of the ravages of syphilis, would hesitate over trouble and expense if convinced that good results could be obtained thereby? The atlas of syphilimetry and the articles by the same author which preceded it should be studied by all who have to do with the pathology and treatment of syphilis.

Syphilis. Tome I. Généralités et Syphilis de l'Adulte. By EMILE SERGENT, L. RIBADEAU-DUMAS, L. BABONNEIX. Paris: A. Maloine et Fils. 1920. Pp. 595. Fr.28.

THIS volume is the result of a collaboration of several contributors, all of whom are well known as authorities on the subject concerning which they write. The first part deals with the pathology, diagnosis, and treatment of syphilis in general; in the second part are sections dealing with syphilis of the different systems of the body, skin, mucous membrane, abdominal viscera and thorax. Each of these sections has been contributed by a different writer, and the result is the furnishing of a vast amount of information from the pens of recognised authorities on the subject. The manifestations of syphilis are so protean that it is difficult for one author to deal with all the lesions for which the *Treponema pallida* may be responsible. For this reason collaboration is essential for the production of an all-round work on the subject, if it is to aim at being authoritative,—and the book under review can be thus regarded. The treatment of the subject is comprehensive, forming a source of reference for those searching for information on some of the less familiar manifestations of the disease.

The chapter on syphilis of the alimentary system contributed by Dr. Favre is especially interesting inasmuch as it treats of lesions, the syphilitic nature of which is frequently missed. In dealing with syphilis of the stomach, Dr. Favre recognises a great variety of forms ranging from a simple catarrh of the mucous membrane to extensive infiltrations, followed by marked deformities of that viscus. So different are these syphilitic lesions that diagnosis is naturally a matter of difficulty. For this reason the author offers the same advice as that proffered by Fournier—i.e., not to search for symptoms characteristic of gastric syphilis, but to bear in mind the possibility of syphilis whenever faced with gastric trouble of obscure origin. As confirmatory evidence the result of treatment is of even greater importance than the Wassermann reaction. It is the fact of such lesions passing so frequently unrecognised, and not their refractory nature, that renders gastric syphilis a serious complaint. Perforation is fortunately, according to the author, a rare complication; the same, however, cannot be said of pyloric obstruction and hæmorrhage. The section on syphilis of the heart and blood-vessels is contributed by Dr. P. Rostaine, and shows that a great advance has been made in the knowledge of syphilitic lesions of these structures since the first observation on the subject published by Ricord in 1845. The important question of syphilis of the central nervous system is discussed

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

"Tar" includes all matter insoluble in water but soluble in CS2. "Carbonaceous" includes all combustible matter insoluble in water and in CS2. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9lb. per acre; (b) 2·55 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved [illegible] the same as published in previous tables.

the author results in a good general presentation of the characteristics of each group of plants, while the search for details relating to any given type is facilitated by the provision of an excellent index and by the illustrations. Plant physiology is dealt with along modern lines, special attention being directed to certain newer theories which the author regards as fundamental and therefore elementary (see Preface). We think, however, that in teaching the early stages of botany it is better to direct the attention of the student mainly to experimental methods, limiting the discussion of theoretical speculations at least to such views as have obtained a full measure of recognition. For the more advanced student the newer speculations have much interest, and these readers will welcome the useful summaries given in this text-book.

The volume is fully illustrated, the majority of the figures being good and clear. The floral diagrams of the family Liliaceæ (Figs. 1323 and 1330) are incorrectly placed with respect to the axis. Some of the diagrams seem to have only a remote connexion with the text, and one or two of them are rather overcrowded with detail. The book as a whole is a useful addition to English botanical literature and should find a place in the library of students taking a university course in this subject.

JOURNALS.

Journal of Physiology, Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LV. 1921. Nos. 1 and 2. Cambridge University Press. Pp. 1–158. 14*s*.—The Substances needed for the Growth of a Pure Culture of *Colpidium Colpoda*, by R. A. Peters.—The Replacement of Potassium by Uranium in Perfusion of the Heart, by H. Zwardemaker. The author has already demonstrated that uranium or any other radio-active element can be substituted for potassium in Ringer's fluid in perfusion without disturbing the automaticity of the heart of the frog and the eel, provided that the amount of the element substituted is radio-equivalent to that of potassium in the fluid. The amount of uranium required for effective substitution in the frog is not the same in summer and winter—i.e., there are factors, with which the author deals, which increase or decrease the effect of radio-activity.

The Influence of Extension and Temperature on Heat Production in the Muscle Twitch, by Y. Doi. The author confirms the statement that heat production reaches a maximum at a certain moderate extension. Before this optimal length the heat production increases, and beyond this it decreases with increasing extension. The optimal extension of a muscle is shorter at a lower temperature than at a higher. The heat production is larger at a lower temperature than at a higher, except at very extreme extensions.—The Influence of an Acute Anoxic Anoxæmia on Respiration and Circulation, by the same author. The writer's experiments were carried out on cats anæsthetised with urethane. When the cat is subjected to an oxygen-pressure lower than that of the ordinary atmospheric air the volume of blood passing through both lungs per minute is the same as that when the breathed air is normal, regarding the hæmoglobin concentration as the same. After a short exposure to a low oxygen-pressure the cat takes up the same amount of oxygen as that in normal air. On an acute anoxic anoxæmia the volume of the respiration per minute increases. When the cat is exposed to a deficiency of oxygen the frequency of respiration and pulse increases, and the output of each heart beat decreases. The decrease of the percentage saturation of oxyhæmoglobin in the arterial and venous blood is nearly parallel in the state considered, so that the difference of oxygen content of the arterial and venous blood is fairly constant.

On the Amount of Heat Liberated by *Bacillus Coli* when Grown in the Presence of Free Amino-acids, by C. Shearer. It had been found that *B. coli* grown on various culture media produced little or almost no heat when grown on tryptic broth. This and other observations led to the author's experiments, with the result that he found that when *B. coli* is supplied with abundance of free amino-acids already prepared the process of building these into the living protoplasm is an extremely economical one, in which little energy is used. The process is three to eight times more effective than the growth of the same organism on glucose-peptone broth. Tryptic broth that has been digested for a short time (one week) produces considerably more heat with *B. coli* than the same broth digested for a long time (three to eight weeks). The difference would seem to be far too great to be accounted for by the extra hydrolysis the polypeptids had undergone in the three to eight weeks' fluid. The pathological process of metabolism, either with tryptic digest or in any other culture fluid, is always accompanied by a greater liberation of heat than is given by the same amount of growth on the same medium under normal healthy conditions; pathological growth is thus less economical than normal growth.

The Physiological Changes Produced by Radium Rays and Ultra-Violet Light in the Eggs of Nereis, by Alfred C. Redfield and Elizabeth M. Bright. It is already known that the exposure of the unfertilised eggs of *Nereis limbata* to the β or γ rays of radium brings about certain very definite changes in the process of membrane formation and jelly secretion which ensues when the eggs are subsequently fertilised. The authors set out to observe the effects of other kinds of radiation on this process, and the nature of the changes thereby produced in the egg, and to explain the specific differences in the effects of different radiations. Elaborate details are given in comparison of different kinds of radiation and as to the methods of obtaining the rays. It was found that a rays and ultra-violet light resemble β and γ rays in altering the process of membrane formation and jelly secretion in nereis eggs, but the process is unaffected by wave lengths of light shorter than 3000 A.V. The changes produced are limited to one side of the egg. Radiation alters the process of jelly-secretion and membrane formation by causing a certain quantity of the jelly substance to be retained within the perivitelline space of the egg. The retention of the jelly substance is due chiefly to an alteration in its physical properties. There is no reason to believe that a change in the permeability of the membrane of the egg is an important factor in causing this retention. The differences in the effects of the radium rays and ultra-violet light on membrane-formation, on the induction of artificial parthenogenesis, and on the prevention of development are due to differences in the penetrating power of these radiations, and the failure of visible light to affect the egg is attributable to the limited absorption of those wave lengths by protoplasms. Since the change produced in the egg is simple in nature, it is justifiable to suspect that some common mechanism underlies the effects produced by these different radiations.

The Coagulation of the Blood. I. The Rôle of Calcium, by H. W. C. Vines. In all theories of coagulation the presence of calcium salts is recognised as an essential factor, and it is generally held that the activity of calcium depends on its presence in the ionised form. The author's experiments were made on normal human blood. He finds that calcium is present in normal blood in two forms, ionised and combined; the latter is transformed into the ionic state during coagulation. The addition of oxalate, citrate, or fluoride to normal blood in amount chemically equivalent to the total calcium of the blood does not inhibit coagulation; this indicates that the presence of ionised calcium is not essential to the clotting process. The anticoagulants described all inhibit clotting primarily by combining with the calcium-containing complex; the amount of anticoagulant required to neutralise the action of the complex is in each case in excess of the chemical tuberculosis for all time? It is probable that we have underestimated the numbers concerned, for in addition to the figures given, thousands of new cases would continue to be added annually to the lists of candidates for segregation.

Another calculation may be based on the opinion of no less an authority on tuberculosis than Calmette. He has recently expressed the view that everyone who reacts to the tuberculin test—even though apparently healthy—is an intermittent spreader of tubercle bacilli, the more dangerous because unsuspected. The overwhelming majority of the adult population of civilised communities being tuberculin-positive, we are faced with the comic-opera problem of locking up more than 90 out of every 100 adults. Even the most fanatical advocates of segregation must experience some diffidence when the problem is seen from this point of view. To distinguish between the various degrees of "dangerousness" among the tuberculin-positive would be an invidious task, leading to unfair discrimination as between rich and poor. For a patient's banking account must affect his classification as "dangerous" or "safe," and any legislation conferring summary powers over the tuberculous would create violent opposition from the bulk of a community. It has been facetiously, but with quite sound logic, suggested that if the "segregationist" must have his way and part the tuberculin-positive from the tuberculin-negative, it would be simpler for the majority—i.e., the tuberculin-positive to remain at home, and for the minority to be removed to some hypothetical place of safety. This suggestion may seem paradoxical and fantastic, but has not the principle of segregation of the non-tuberculous already been put into practice? Is not this the principle adopted consciously or unconsciously whenever a slum child is given a holiday in the country? It is amazing to find the success achieved by the segregation of lepers in Norway seriously cited as an argument in favour of segregating consumptives. Considerably less than 1 per cent. of the population in Norway being lepers it was comparatively easy to control this small minority. In the case of tuberculosis, however, this proportion is reversed, and the tuberculin-positive are in a majority whose exclusion from the community is impossible. In many points the comparison with leprosy is misleading, and we should temper our judgment of Koch's patronage of this analogy by the reflection that it dated from a time when tuberculosis was still regarded as a weed with comparatively short roots. Thanks to v. Pirquet, we no longer measure the disease only in terms of months and years; we think in decades. Indeed, some of the factors determining the outbreak of active tuberculosis would appear to be traceable to a "tuberculous tendency" in certain of our ancestors. Confining ourselves to the present generation we find a disease running for a long time a clinically, but not necessarily a bacteriologically, subterranean course. Sometimes, indeed, quite often, the patient lives with his disease for more than 50 years, during which he intermittently disseminates tubercle bacilli. The few months he may take to die in an isolation hospital are but a brief fraction of his sputum-positive career. Without hospital segregation he would die in the home in which he had done all the harm his disease was capable of doing long before his working capacity broke down.

Before we commit ourselves to a policy of compulsory segregation, we should do well to weigh the extent to which it would force the disease into subterranean channels, and prevent that early diagnosis which every one familiar with this disease considers the first essential to successful treatment. The subject is not one for dogmatic pronouncements, but we have a shrewd suspicion that if tuberculosis comes to be regarded by the working classes as a legalised reason for compulsory breaking up of their homes, they will take every possible step to evade early diagnosis and the treatment which may terminate in segregation. And if tuberculosis comes to earn the unenviable stigma of such hidden diseases as syphilis and gonorrhœa, we may rest assured that its conquest has been deferred for many a day. We do not know what view the Conference will take of these complicated problems, but they will do well to approach them, not in the well-meaning but primitive lock-'em-up spirit of the policeman, but with a statesmanlike grasp of the many considerations that must be taken into account.

◆

The Resurrection Man.[1]

Burke and Hare were murderers, of whom the former was hanged at Edinburgh on Jan. 28th, 1829, and the latter, having been called as a witness by the Crown, escaped trial. They were not body-snatchers or resurrectionists, Mr. Roughead points out, and there is nothing to show that they had ever even attempted that gruesome occupation. They had done what the body-snatcher did for the anatomist, by bringing bodies to his lecture room in days when the necessity for instruction in anatomy was recognised as part of the medical curriculum, but when the law made practically no provision for a supply of subjects. Burke and Hare, however, did not rob graves of the dead. They suffocated the living, after fuddling them with drink, packed their bodies in boxes before they were stiff, and delivered them almost before they were cold at "Dr. Knox's Rooms for Practical Anatomy," 10, Surgeons' Square. The prices paid ranged up to £10 per body, which was the usual sum, and at least 16 subjects had been supplied by these miscreants within a space of nine months before an honest labourer and his wife, lodging at Burke's, and probably destined for death themselves, found the body of old Mary Docherty lying naked under the filthy straw of the bed, and informed the police. With moderate promptitude, but with no great alacrity and no noteworthy insight into the possibilities of the case, the police began inquiries which resulted in the arrest of the right persons, Burke, Hare, and two female associates of the criminals. The full measure of the iniquity of the gang was not revealed until Hare was sure of his escape as King's Evidence, and even so may never have been wholly discovered. The trial, with its legal argument on the relevancy of an indictment charging three separate murders, and as to how far the accomplice Hare might be cross-examined at Scots law with regard to his own crimes, contains several points of interest to a historian studying the growth of the criminal law. In medical history it occupies an even more important place. The horror it aroused secured the passing of legislation to prevent, so far as possible, the recurrence of the crimes which it revealed, by stimulating into action a legislature which had been fully aware of the needs of science, and had left them to be catered for by the resurrectionist.

The Lancet had done its full share in calling attention to the requirements of the anatomical

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Colchester.

IN Colchester the estimated population for 1920 was 43,007. The birth-rate has jumped from 16 to 22; there were 351 more infants born in Colchester in 1920 than in 1919. Dr. W. F. Corfield draws attention to two important statistical records—viz., a general death-rate of 10·3 and an infant mortality rate of 44·1. The death-rate from tuberculosis is 0·79 for pulmonary and 0·27 for other forms. Of the 47 deaths of infants under 1 year, no less than 25 were attributed to congenital debility and premature birth, showing that there is still room for improvement even with a rate of 44. Dr. Corfield suggests that the slaughter-house of the Coöperative Society should be used as a public abattoir and the other slaughter-houses closed. Food condemned in London as unfit for human consumption has recently been released for cattle or poultry feeding and sent to dealers who sold food for human consumption. "It would be more satisfactory if no dealer in human foodstuffs were allowed to receive condemned unsound food under any circumstances whatever."

The modified regulations for the notification of measles and whooping-cough came into force on April 1st, 1920, and Dr. Corfield thinks the result encouraging. Nursing assistance has been provided for severe cases. Dr. Corfield complains of patients being sent to sanatoriums under the county scheme with their teeth in a bad state. "It is wasting valuable time to send a man with a mouth full of carious teeth to a sanatorium in the hope of materially improving his health." The health visitors act as general health nurses and visit infants, school children, and cases of tuberculosis. Thus overlapping is avoided, and the health visitor has a chance of becoming a friend of the family. The antenatal clinic has made little progress as yet. "It is a definite drawback to the work that the borough council is not the supervising authority under the Midwives Act."

Five cases of ophthalmia neonatorum were notified. Four recovered without damage, but the fifth case resulted in complete loss of the sight in one eye and great diminution in the other. In 1919 it was estimated that 600 new houses were required. Under the council's scheme 28 have been completed and 50 are in course of erection. Overcrowding has to be regarded with a lenient eye. A number of old houses require renovation and some only deserve destruction, "but it is still necessary to leave such hovels standing and occupied until the time comes when house room is not so scarce as it is at the present time."

Margate.

The Registrar-General's estimate of the population for 1920 is 23,243. The death-rate is given as 12·7, the birth-rate as 24·5, the tuberculosis death-rate as 1·4, and the infant mortality rate as 68. Dr. R. McCombe estimates the ordinary population at about 30,000—increased at the height of the season to about 100,000. The principal occupation is catering for visitors, and Dr. McCombe thinks many of the children attending the elementary schools are seriously neglected during the season. A new reservoir to hold 2,000,000 gallons has been approved. The water is from the chalk and of very high bacteriological purity. A considerable extension of the sewerage system has been rendered necessary owing to the extension of the borough. Six steam wagons have lately been purchased to facilitate scavenging. A motor ambulance is needed for the isolation hospital. Tuberculosis is under the care of the county council, and it is mentioned that "the accommodation for patients in sanatoriums is most inadequate." A new infant welfare centre, adapted from an army hut, was opened in September last. Five cases of ophthalmia neonatorum were notified and recovered without permanent injury to eyesight. There are three midwives in practice, two being municipal. "The two municipal midwives are paid a stated salary by the town council and the fees received from their patients are paid back into the borough fund" . . . . "The municipal midwives occupy their spare time in antenatal visiting." They attended 227 midwifery cases during the year.

The housing scheme of the council provides for 300 houses during the next three years. Only four are completed. Dr. McCombe says: "It would seem that some considerable time must elapse before the shortage of houses can be overcome, and it would also appear that the 300 houses to be built in the borough by the housing committee will not satisfy the present demand." In the meantime, there is difficulty in getting existing houses kept in good repair, and "standards are not quite so high as in pre-war days." The total hours of sunshine registered at Margate during 1920 were 1522.

Southwark.

Dr. G. Millson states that the estimated population for 1920 was 187,142; the death-rate was 14·4 (2·0 above that of London), the birth-rate 31·8 (5·3 above that of London); the infant mortality rate was 86, the lowest on record. The death-rate from pulmonary tuberculosis was 1·3, while that for London was 1·01. As in other towns this rate went up during the war years and is now lower than before the war, Dr. Millson says: "Much poverty has existed in the borough during the year. Necessitous children and expectant mothers have received free milk to the extent of £1658 14*s*. 2*d*. The municipal nursery, which accommodates 45 infants, has been always full and four times the number accommodated have applied for admission." Southwark is usually overcrowded but has been more so than usual in 1920. "There are various large housing schemes before the council necessitating the clearance of upwards of 20 acres in the borough. These have been held up for a time partly on account of the inability to provide accommodation for the dislodged population and partly on account of the high price and the difficulty of obtaining building materials." There is no vacant land for building purposes in Southwark.

Very complete tables of statistics and of sanitary work done are submitted from which we extract a few items. The infant mortality rate among illegitimate infants was 156. There were 91 cases of ophthalmia neonatorum notified, but no mention is made of the amount of permanent damage to the eyes or loss of sight resulting therefrom. Of the 243 deaths from pulmonary tuberculosis 147, or 60·5 per cent., occurred in institutions. The hospital-treated diphtheria cases, 440 in number, had a case-fatality of 7·5 per cent., while 17 home-treated cases gave a case-fatality of 23·5 per cent. Dr. Millson advises that measles be again made notifiable. "The maternity and child welfare scheme is in full operation. Of the 14 centres existing at the present time, seven are entirely municipal, three partly municipal and partly voluntary, and four wholly voluntary."

Hove.

In 1920 the population estimated for birth-rate was 46,204 and for death-rate 45,909; the birth-rate was 15·5: "the births always exceeded the deaths until 1913: in the years 1915 to 1919 the loss by excess of deaths over births was 380; in 1920 the births exceeded the deaths by 184." The death-rate was 11·65 and the infant mortality rate 48. "The most troublesome sanitary problem in recent years—viz., the disposal of house refuse—has at last been brought to a satisfactory solution, and the crusher works are in process of erection." "The erection of houses under the council's housing scheme has not yet begun, but this is not the fault of the council." Twenty-four new houses have been erected and 51 additional tenements provided by alteration of houses into flats. "There are many houses still overcrowded, but no other accommodation can be found."

Annotations.

"Ne quid nimis."

MINISTRY OF HEALTH: ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER.

THE annual report of Sir George Newman, the Chief Medical Officer of the Ministry of Health, for the year 1920 was published this week, and, considering the importance and variety of the matter to be reviewed, its date of issue is a remarkably prompt one. The document is a less bulky one than that published last year, when the machinery of the Ministry came in for description. It deals comprehensively and in a popular manner with the state of public health during 1920, as revealed by official statistics and by the work and records of the Ministry, and a summary has been distributed to the lay press; this has proved a judicious course of procedure, for in this way the medical history of the year has been revealed in brief to all. That history reveals no alarming epidemic nor any decline from a steady improvement in general health. Sir George Newman is insistent upon two points as the basis of ministerial policy: consolidation and strict economy. Every pound expended on our medical services must be made to yield the full value of a pound. A rise in birth-rate, a fall in infant mortality, an almost negligible notification of smallpox, absence of alarming epidemics, and a decline in tuberculosis are cheering pieces of information to be found in the report.

With regard to V.D. the report recalls the fact that the policy of the Ministry is based largely on the findings of the Royal Commission of 1916; confidential registration of the cause of death has not been found possible, but the other important recommendations of the Commission have been carried out. The effect of communal action is thus stated:—

> (1) There were a total number of new cases treated in clinics (including non-venereal cases) of 103,000. The total number of attendances was 1,488,000.
>
> (2) The rapid rise of "new" cases in 1918–1919 did not continue. The number (quite untrustworthy as a basis for calculations) remained stationary.
>
> (3) The total attendances have increased greatly, the clinics being more appreciated as time passes.

The circumstances of insurance practice are explained in the report, while, though criticism is not deprecated, the fair reminder is given that the service having grown up under unpropitious circumstances has not had a fair chance of arriving at the hoped-for all-round efficiency. A new scale of medical remuneration and the use of record cards have been introduced: the latter innovation was received in certain quarters with opposition, the value of statistical information being counterpoised by the ethical difficulties, of which more, it appears, may be heard. The limitation of panel lists and the new facilities for choice of doctor must have a beneficial effect upon a service which ministers to about one-fifth of the whole population, for the number of insured persons entitled to such benefit in 1920 was, we are told, 13,873,000, while computations show that about 60 per cent. of these people actually received treatment.

The report covers a number of other important functions of the Ministry, either in integral chapters or as appendices, and we shall have constant occasion to make further reference to it.

DERMATOLOGICAL PROGRESS.

IT is no exaggeration to say that much of dermatology is still a closed book to many medical men. That this should be so is partly due to the unnecessarily complex nomenclature of skin diseases; partly to the fact that even an elementary knowledge of the subject is seldom required in the qualifying examinations; and to some extent because an "eye for skins," like an "[illegible] for music," though not precisely an innate gift, can only be acquired with perseverance and use of all opportunity. This is regrettable, since, apart from definite eruptions, changes in the texture, colour, and secreting functions of the skin are often the earliest signs of ill-health, and may unmask some abnormal condition which, if neglected in its beginning, may lead to serious disease.

In his Lumleian lectures for this year, two of which we have already published and the third of which we publish this week, Dr. Arthur Whitfield shows with admirable clearness how modern research is tending to raise dermatology to its rightful place in medical science; and in the light that is now being thrown on their causation the nomenclature and classification of skin eruptions is becoming progressively simpler. These lectures make fascinating reading, and some of the case-histories of patients with eczematous dermatitis due to external causes afford the amusement of good detective stories. The importance of focal sepsis, bacilluria, and indicanuria in the ætiology of some skin diseases is rightly insisted on, but Dr. Whitfield is not only an acute observer, he is also a very careful critic both of his own work and that of others, so that his conclusions may be accepted with confidence. Of particular interest are the cases he quotes of autosensitisation—namely, those in which a generalised eruption may follow severe bruising of the tissues, and those in which the fluid from the vesicles of an acute eczema is irritant to the patient's own skin but innocuous to that of a healthy person. The question, too, of foreign protein sensitisation, which is being exhaustively studied in America, certainly deserves the closest attention both from the dermatologist and the general physician, but it is beset with difficulties, and the interpretation of the phenomena already observed is, as Dr. Whitfield points out, by no means clear. Further research in the subject may show that it is of far greater importance than at present seems likely, and it is one of particular interest to the dermatologist, since cutaneous eruptions are some of the commonest reactions that occur as a result of protein sensitisation. Dr. Whitfield deserves credit alike for his own original work and for having shown so clearly that dermatology is now securely based on scientific investigation and reasoning.

THE COMPOSITION OF MILK.

A QUESTION was recently asked in the House of Commons on the prosecution of farmers and dairymen for supplying milk deficient in fat, and it was suggested that the basis of any prosecution should be not one or two but a series of tests to eliminate the possibility of unfairness. Sir A. Griffith-Boscawen admitted that the subject was of interest.

The value of milk as an article of food depends upon (1) its chemical composition—i.e., upon its content in protein, carbohydrate, and fat; (2) its content in the three accessory food factors or vitamins. Its food value is generally calculated from the composition of protein = 3·3 per cent., carbohydrate = 4·8 per cent., and fat = 3·6 per cent., but in reference to its sale its value is based upon a minimum of 3 per cent. fat and solids not fat of 8·5 per cent. It is well known that the chemical composition of milk varies greatly; not only does the fat vary, but also the protein and carbohydrate. The greatest variations occur in the fat content, figures having been recorded from under 2 per cent. to above 6 per cent. The variations in protein and lactose are not so well known, since these constituents are not regularly determined, but they may amount to about 1 per cent., though usually about 0·5 per cent. The variations are due to several conditions such as time of milking, morning, afternoon, or evening, period of lactation, state of nutrition, and nature of nutrition of the animal; consequently it is very difficult to set up a really satisfactory standard for milk. On the whole the standard of 3 per cent. fat is a satisfactory figure, as usually the mixed milk from a herd of cows is sold on the market. The high fat content of the milk of some animals will balance

THE LANCET.

LONDON: SATURDAY, JULY 23, 1921.

Opening of the B.M.A. Meeting.

The second annual meeting of the British Medical Association to be held under post-war conditions is drawing to a close. It has been a notable gathering in many respects, and especially in its tacit recognition of medicine as an integral part of human life and endeavour. At the opening session of the business meeting the Lord Mayor of Newcastle-on-Tyne, in welcoming the medical profession to the metropolis of the North, compared the present gathering with the previous Newcastle meeting of 1893, calling attention to the closer grip of medicine on public affairs which has come about in the intervening 30 years. And Dr. T. W. H. Garstang, in reply, foreshadowed still further and swifter change in the years immediately ahead of us. The public addresses were in the same strain, for Prof. David Drummond, President this year, devoted half of his opening address to the relation of the doctor to the public, recognising in no carping spirit how much still remains to make this relation a perfect one. "We are a scientific and progressive profession," claimed Dr. Drummond, but immediately asked, "Can we do more than we are doing, and thus progress more rapidly?" He then gave his reasons for thinking that such progress consists in increase of knowledge and its wider diffusion, and that, as these occur, the position of medicine in the State will be recognised at its true value. And finally Sir Thomas Oliver dealt with the boundless possibilities, as yet almost untouched, of industrial hygiene. Sky and street and factory revealed to the stranger in Newcastle that much satisfaction awaits the unflinching application of medical science—even the knowledge which we already possess—to the daily civic life.

The business meeting was notable for two decisions likely to have marked repercussion on affairs outside. A recent case of violation of professional secrecy in a civil court had focussed attention on a question already burning brightly at the Cambridge meeting. Representatives were all but unanimous in going far beyond the recommendations of their Council in asking the Association to use all its power to support a member who refuses to divulge, without the patient's consent, information obtained in the exercise of his professional duties. It was admitted that on occasion such refusal may result in making criminal conduct more difficult to detect—at any rate cases were cited where this might occur—but substantial benefit to the public accrues from the sense of security given by the Hippocratic oath; thousands of venereal cases might, it is alleged, forgo treatment altogether rather than run the risk of betrayal, and there was no doubt in the meeting as to the balance on the profit and loss account. Reduced to this simple proposition no difficulty is likely to occur in practice. As it is the lawyer and the priest are not protected by statute, but no one questions the lawyer as to what the prisoner has told him and the priest would be punished for divulging. Possibly the General Medical Council might assist by offering to remove from the official register the name of any practitioner who laid bare his patient's secrets on the invitation of a judge. Short of this, the medical man's disability, as it might be called, would soon become generally accepted, and instead of attempting to extract evidence from him on duress, against his regard for professional honour, the prosecution would explore other if less direct and easy channels. Medical evidence as soon as it begins to deal with clinical opinion has always proved difficult to handle in a court of law; a consultation on a case may be trying even for a medical panel. And it can hardly be to the detriment of justice if for the present the value of the Wassermann test and the differential features of the spirochæte group are ruled out of court. Another year must, however, pass before this decision of the Representative Meeting can become the considered policy of the British Medical Association, and no doubt the medical Members of Parliament will assist the Council of the Association in finding the best means of reconciling medical and legal views to the benefit of the community.

The other decision was definitely to close the door just left ajar at Cambridge last year, on the affiliation of the Association with any non-medical bodies. The value of identity and individuality was felt to be so great an asset that no weakening of these attributes could be admitted for the sake of speaking to the Minister of Health with the united voice of all the health interests. Naturally it was not intended thereby to rule out the benefit of threshing out certain mutual difficulties before presentation. Public men were regarded as being duly impressed by the large individual membership of the Association and the means taken under its present constitution of obtaining a representative opinion. Federation with any other medical bodies, apart from the overseas branches, was not ruled out, but the time was held to be inopportune for considering the matter. Both these decisions were taken, as we have indicated, after full discussion and with a strong sense of responsibility.

◆

Compulsory Measures against the Tuberculous.

Next week, July 26th, 27th, and 28th, a Conference of the International Union against Tuberculosis will be held in London at the Institution of Civil Engineers, Westminster. One of the subjects for discussion is the prevention of spread of infection. Of the many paths that may lead to this goal, most are still practically unexplored, and among these is compulsory segregation. This is being preached by a certain section of the medical profession as the surest means towards stamping out tuberculosis. As this proposal involves encroaching on the liberty of the individual, we should do well to scrutinise it carefully, and from every possible aspect before we commit ourselves to it. In a recently published book on tuberculosis a well-known medical author has written: "Segregation of dangerous cases must somehow be effected." Now, what are "dangerous cases," and what proportion of the whole community do they represent? An answer may be found in one or other of the following calculations. In 1919 there were 46,312 deaths in England and Wales from all forms of tuberculosis. Assuming that 10 active, living cases of tuberculosis exist for each annual death, we obtain a total of 463,120 more or less "dangerous cases." Is the nation prepared to lock up nearly half a million persons in the by no means sure hope of stamping out in the animal inoculation experiments only a small percentage (5·7 and 8 per cent. in two different series) were positive. The author concludes that the acid-fast bacilli so frequently found, microscopically, in centrifuged blood by other workers are not virulent tubercle bacilli whatever else they may be.

And at this point we must be content for the moment to leave the question. Tubercle bacilli have been sought for in many hundreds of blood specimens withdrawn from the vein in the usual way, but with the use of the guinea-pig inoculation test only rather less than 10 per cent. of positive findings have been recorded. We now require to know whether these positive cases represent a class of case separate and distinct from all other cases of tuberculosis, or whether they indicate a phase in the clinical history of all tuberculous cases—a phase during which bacilli are discharged into the blood stream and there rapidly destroyed.

DETACHMENT OF THE RETINA.

THE problem of detached retina is one of the most difficult in ophthalmology. Neither as to its pathology nor its treatment is there any general agreement, and in spite of isolated instances of cure, to which many ophthalmic surgeons can testify, the sad fact remains that in the vast majority of cases an eye in which the retina becomes detached inevitably goes blind. At any rate, cases of cure are sufficiently rare to justify the publication of any case such as that reported in another column by Mr. Foster Moore. At the same time the word " cure " can hardly be applied to a case which, apparently, has only been under observation for a few weeks since the reättachment of the retina was observed. A committee of the Ophthalmological Society, reporting on the subject in 1916,[1] decided to consider a case " cured " when the retina had gone back into position and stayed there for six months. To some of the committee even this period seemed too short, and the report expressed the opinion that it must certainly be regarded as the irreducible minimum. Cases, indeed, are common in which after rest in bed or some form of operative treatment the extent of a detachment becomes much diminished, and occasionally it may even disappear altogether, only to relapse as soon as the patient resumes a normal active life. The number of published and unpublished cases of " cures " collected by this committee was 85. It should be added, however, that not every uncured case of detached retina goes on rapidly to complete blindness. Some eyes in which there is still a demonstrable detachment retain even for years a certain amount of useful vision.

There are types of cases in which the prognosis is much less unfavourable. In cases following a blow, in which the cause of the detachment is an effusion of blood beneath the retina, the prognosis is favourable. The same is true of another class of cases to which Mr. Moore calls special attention—viz., detachment occurring with renal retinitis, and especially in pregnancy cases. In discussing the pathology and cure of detached retina these " symptomatic " cases are generally excluded, and attention is directed solely to the so-called " simple " cases, which, after all, constitute the great majority. As to their pathology two facts are known with certainty. The attachment of the retina proper to its pigmentary epithelium layer is so loose that the space between them is always a potential cavity, which in cases of detachment becomes an actual one containing fluid. The second fact is that the majority of these cases, but by no means the large majority, occur in myopic eyes—i.e., in eyes in which the retina has become abnormally stretched, and the vitreous cavity abnormally enlarged. Further, in a small proportion of these cases rents or holes in the detached retina are observed ophthalmoscopically. Again, in a few cases bands in the vitreous are seen, apparently attached to the separated part of the retina. Starting from these facts, different theories of the causation of the disease have been held. Graefe held that it was due to exudation into the inter-retinal space from diseased choroidal vessels. Deutschmann maintained that practically all cases are due to the traction of vitreous bands on the retina causing rents. Raehlmann put forward a theory of an abnormal osmotic pressure resulting in an excessive current of fluid from before backwards into the inter-retinal space. Now, none of these theories carry us much further towards a successful method of treatment. Deutschmann, indeed, himself claimed a large percentage of cures by his method of dividing the vitreous bands, but his claims entirely lack confirmation. Of the methods of treatment now generally in vogue the first place should undoubtedly be given to rest in bed. In recent cases, indeed, this by itself diminishes the extent of detachment and temporarily improves the visual acuity. In exceptional cases it appears that a detachment can be really cured by this measure alone, as in two cases reported by Mr. J. B. Lawford in 1915.[2] It must be added, however, that there are other exceptional cases in which a detachment appears to have been cured without any treatment whatever. The second place in treatment will generally be given to evacuation of the subretinal fluid, either by puncture with a Graefe knife or by the cautery. The unfavourable comment made by Mr. Moore upon this operative procedure is rather surprising. With regard to subconjunctival injections they have generally been employed as an adjunct in the way of treatment, and their action has been attributed somewhat loosely to counter-irritation. It has been found experimentally that an injection beneath the conjunctiva is followed by a marked increase in the albuminous contents of the aqueous. Whether or not Mr. Moore's case is an instance of cure from rest in bed or from subconjunctival injections, or whether it is a permanent cure at all, time and further experience will show. We are glad to report the case.

FRIENDLY SPAS.

IN the early days of the present month of fine weather, Sir Henry Lunn arranged for a group of 20 representative British medical men to visit Aix-les-Bains and a number of the Swiss watering places. France and Switzerland are justly proud of the facilities which they are able to offer for hydrotherapy and aerotherapy, under conditions of great natural beauty, and the grave depression which these spas are undergoing is due to political and economic causes, and not in any sense to individual failure. The state of the money market has deprived the spas of whole sections of their usual clientèle, while the Swiss themselves are largely seeking recreative holiday in adjacent countries where the exchange is in their favour. It is not unnatural, therefore, that Aix-les-Bains, Ragaz, and the Engadin should look to an influx of patients from English-speaking countries to retrieve their fortunes, the more so as it was English custom which set going their prosperity a generation or more ago. Of the warmth of the reception which awaits them there no doubt can exist; the hospitality lavished on the British medical visitors was evidently something more than a laudable desire to make known certain attractive therapeutic wares; it was an earnest of the valuable team-work of hotelier, spa physician, and skilled attendant which is at the command of every patient and which has brought the practice of balneology to a level behind which its scientific basis sadly lags. The immediate future is likely to see this made good, for at the principal baths in the Upper and Lower Engadin scientific work is being done by men of professorial rank in connexion with the universities of Berne and Zurich, and at Aix-les-Bains the local medical society is keenly alive to the need of showing that medicinal schools and the way in which they were being met. In a leading article,[2] published when Burke and Hare were actually committing their last murders, we commented upon a case of body-snatching then recently tried at Norwich.

---

[1] Trans. Ophthal. Soc., 1916, vol. xxxvi.

[2] Trans. Ophthal. Soc., 1915, vol. xxxv.

> "Body-snatching is no doubt a disgusting offence, and not the less disgusting because rendered necessary by the state of the law regarding anatomical dissection."

We protested also against the sentence of hanging being coupled with an order that the body of the culprit should be dissected.

> "Let the legislature repeal that provision in our statute book which associates the idea of dissection with that of punishment for crime."

Within six months of these sentences being printed Burke had been hanged and his body dissected, after lying in gruesome state for thousands of visitors to inspect at the anatomical theatre to which it was consigned. Later we pointed out that either bodies must be provided in a manner acceptable to public sentiment, or dissection must be forbidden. The present laws, under which, it may be added, there is no plentiful supply of subjects, followed. The knowledge that we possess of this important epoch in the story of medical education is scattered through many books, pamphlets, and newspapers, and no better editor could have been chosen than Mr. Roughead to condense the information available within the limits of his recently published volume. The nine chapters of his introduction are convincingly lucid and judicial, and he appears to state nothing that is not well authenticated. The chapter which deals with "the body-snatchers" is medical history, not merely because the horrible trade of the professional resurrectionist provided subjects for dissection, but because medical students of that day, led away by zeal on behalf of their schools, vied with the professional, took the same risks in providing "subjects," and incurred the same odium.

The question arose of how far Dr. Robert Knox, an able teacher, but with no very high reputation outside the circle of his pupils, may have suspected the source from which his lecture room was being supplied, and may deliberately have shut his eyes and asked no questions. Only one of the three cases charged in the indictment was tried. If that of Mary Paterson, or "Daft Jamie," had been taken instead, or if there had been an acquittal in the first case, Knox would inevitably have been called as a witness and so would his three assistants, one of whom as Sir William Fergusson, Bart., F.R.S., was destined to be President of the Royal College of Surgeons of England. It is difficult not to acquiesce in the view which Mr. Roughead so temperately puts forward. Two men unconnected with the recognised resurrectionists sold to Knox in nine months 16 absolutely fresh corpses, none of which had been buried or presented any appearance of death from natural disease. They had all been killed in the same way, the murderer lying on the victim's body and compressing with his hands the nose and mouth. They were examined at once to see if they were suitable for purchase, and they were afterwards dissected. The evidence of criminal handling may not have been conspicuous. Knox would seem to have made no inquiry as to how the bodies, which arrived so opportunely and at such short intervals, were obtained. Had he no suspicion? Although no inquiry that can be called conclusive was ever held, the medical profession and the public formed their own opinion, and he found his position as a teacher gone. The boys in the street sang: "Burke's the butcher, Hare's the thief, Knox the boy that buys the beef." Knox quitted Edinburgh and died in obscurity. Those who read Mr. Roughead's book are invited to note the dates given, when they will find it difficult to realise how recent are the almost unbelievable events that he recalls. It was less than a hundred years ago that the resurrectionists carried on their horrible trade, and Burke and Hare trafficked in the corpses of their victims. The Anatomy Act of 1832, which recognised the needs of science and rendered body-snatching unprofitable, was passed by legislators who should have grandsons, at any rate, now living. Among members of the medical profession who have passed middle age must be some who lived in London when Knox was ending his days in poverty at Hackney. Any of these as a child may have had pointed out to him by his nurse in Oxford-street the sightless beggar who by repute was Hare, blinded through being thrown into a lime pit by his indignant fellow workmen.

MEDICO-PSYCHOLOGICAL ASSOCIATION: ANNUAL DINNER.

On June 13th the annual dinner of the Medico-Psychological Association of Great Britain and Ireland was held. About 150 members and guests of both sexes were present, and the function was successful not only as a reunion of medical officers engaged in the study of psychological medicine, but as a gathering at which representatives of diverse branches of one great profession met as host and guest. Dr. Hubert Bond, the president of the Association, was in the chair, and the many distinguished guests included the Chief Medical Officer of the Ministry of Health, the secretary of the Medical Research Council, the presidents of the Medico-Legal Society, the Royal Society of Medicine, the Eugenics Education Society, the Society of Medical Officers of Health, the Medical Society of London, the Federation of Medical and Allied Societies, the Director-General of the Navy and of the Army Medical Services, the Vice-Chancellor of London University, while a large number of distinguished alienists acted as hosts. The non-medical guests included also the Lord High Chancellor and the chairman of the Shell-Shock Committee. The occasion was unique in that never before, during the 80 years existence of this Association, has its president been an active Commissioner in Lunacy, though more than one president has subsequently become a Commissioner. The occasion marks the good feeling that exists between the Board of Control and those engaged in work in mental hospitals, and Dr. Bond's year of office as president should serve to maintain and increase these friendly relations. It also, we hope, will mark that modification of the lunacy laws in the interests of recoverable cases, the need for which Dr. Bond has ably pointed out.

Mining Dangers Research Board.—Mr. W. C. Bridgeman, Secretary for Mines, has announced the appointment of a Mining Dangers Research Board to direct the research work of the Mines Department into the causes of mining dangers, and to reorganise the existing arrangements for such research at the Mines Department Experimental Station. The members of the Board are: Mr. W. Walker, Director of the Health and Safety Division, Mines Department (chairman); Mr. T. H. Mottram, Chief Inspector of Mines; Sir R. A. S. Redmayne; Mr. Thomas Richards; and Prof. R. V. Wheeler, director of the Mines Department Experimental Station. The Board will have the assistance of Sir Walter Fletcher, and Dr. C. H. Lander, assessors appointed by the Medical Research Council and the Scientific and Industrial Research Department respectively.

---

[2] The Lancet, 1827–1828, vol. ii., p. 659.

of the British Red Cross Society was taken over on Oct. 20th, 1914, by the Joint War Committee, and the late Mr. Edmund Owen was appointed to coöperate with Sir Frederick Treves, who was then in charge, Sir William Bennett succeeding Mr. Owen at his death in 1915. The total number of doctors engaged by this department for service at home and abroad was about 400, and, in addition, many local appointments were made. Thirteen units, consisting of medical officers, dressers, nurses, and orderlies were sent out to France and Belgium before October, 1914, and six later in the same year. Thenceforward no further complete units were sent to France, though several were despatched to more distant countries. The provision of stores to Red Cross hospitals and additional comforts to the whole army is described year by year. A chapter on ambulance contains excellent pictures of interiors of bacteriological laboratory, dental surgery, soup kitchen, and workshop cars. The account of the development of the Voluntary Aid Department is of special interest, and will be read perhaps more widely than any other section of the report. The establishment of the King George Hospital and of the auxiliary home hospitals and convalescent homes, hospitals, and camps is described, and notes on the after-care of disabled men, the central work rooms, the Red Cross library, and miscellaneous grants to auxiliary bodies complete the section of the report dealing with headquarters work and finance. A detailed account. arranged geographically, of work abroad is then given. The next section describes the efforts made on behalf of the wounded and missing, and prisoners of war, and is followed by a brief note on the demobilisation schemes carried out by a board presided over by Sir Aurelian Ridsdale. The report, which is signed by Sir Arthur Stanley and Mr. Evelyn Cecil, M.P., concludes with a few words on the satisfactory relations maintained between the Joint War Committee and the Government, a tactful note on the question of awards of honours, and an appreciation of the work of the Committee from the Director-General of the Army Medical Service. Twelve appendices enumerate the auxiliary home hospitals, work parties, &c., and give particulars of the Geneva Convention and the Hague Conference. Various specifications and local reports are also incorporated, and an index, extending over 34 pages, completes a report of which it need only be said in praise that it is as adequate as the work it describes was wonderful.

PUBLICATION of Dr. Golla's second Croonian Lecture, delivered before the Royal College of Physicians of London, has been postponed until next week.

ON Monday, July 25th, at 5.30 P.M., Dr. M. Diamond, Chayes post-graduate instructor at the Dental Institute of New York, will deliver a lecture and give a demonstration "On Some New Phases of Old Problems in Dental Reconstruction" at the Royal Society of Medicine, 1, Wimpole-street, London, W. Admission is free to all interested.

THE thirty-sixth annual meeting of the Caledonian Medical Society will be held in the hall of the Royal College of Physicians, Edinburgh, on Friday, July 29th, at 3 P.M., under the presidency of Professor William Russell. The annual dinner will take place the same evening in the Caledonian Station Hotel.

INDEX TO "THE LANCET." VOL. I., 1921.

THE Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1 and 2, Bedford-street, Strand, W.C. 2.

BRITISH MEDICAL ASSOCIATION.

ANNUAL REPRESENTATIVE MEETING AT NEWCASTLE-ON-TYNE.

FRIDAY, JULY 15TH.

THE business meeting opened at 10 o'clock on Friday morning, July 15th, with a full attendance of representatives, in the King's Hall of the Armstrong College. Two women representatives were present. The room was simply but conveniently arranged, although the acoustics left much to be desired. Behind the platform two posters were in evidence, one tracing the increase in membership of the Association year by year throughout its history, the other an appeal of the Newcastle School of Medicine to clear its debt and enable it to pay adequate salaries, to endow professorial chairs, and to provide necessary accommodation for students. Dr. T. W. H. GARSTANG presided over the gathering, as last year. At the outset he introduced the President-elect, Prof. DAVID DRUMMOND, who extended a hearty welcome to representatives on behalf of the North of England Branch of the Association.

Representatives of the Press.

Standing orders having been adopted, a motion was brought forward by the chairman of the Agenda Committee that representatives of the press should be admitted on the understanding not to report any matters which the meeting decided to regard as private. This motion was passed nem. con., after three adherents only had been found for an amendment by Mid-Cheshire that the lay press should be excluded altogether, a précis being supplied to them for publication. Testimony was given to the fairness of the press on previous occasions in respecting the wishes of the meeting.

Future Arrangements.

The annual report of the Council, with the balance sheet for 1920 and the budget for 1921, having been received, it was unanimously agreed to elect Sir WILLIAM MACEWEN, F.R.S., Regius Professor of Surgery in the University of Glasgow, as President of the Association for 1922–23, and to hold the annual meeting of 1922 at Glasgow, and that of 1923 at Portsmouth. Sir HENRY CRAIK, M.P. for the Scottish Universities, was elected an honorary member of the Association.

State Visit from the Lord Mayor.

At this point the proceedings were interrupted to receive a state visit from the Lord Mayor of Newcastle, who recalled the previous annual meeting in the city of 1893, when medicine was by no means taking so prominent a part in public affairs. The British Medical Association he described as one of the best organisations in the world, and he congratulated the metropolis of the north on having produced not only the president-elect but the chairman of Council, Prof. R. A. BOLAM, and the medical secretary, Dr. ALFRED COX. In replying, Dr. GARSTANG admitted the very rapid changes going on in the relations between the medical profession and the public.

The Year's Finance.

On the motion by the treasurer, Dr. G. E. HASLIP, that the annual financial report be received, a lively discussion ensued. The meeting was invited to regard as a modern rake's progress the overspending of £23,000 in a single year when the total assets of the Association did not exceed £150,000; but only four representatives inclined to this view. On the other hand, a motion expressing satisfaction with the present financial position was withdrawn by common consent. Dr. Haslip pointed out that salaries had increased by £5000, and the outlay on paper by £2000; he thought that journalistic ability might condense the reports issued, and so effect some economy. Mr. E. B. TURNER voiced the general opinion that things must cost more, and there was no help for it. It came out in discussion that no part of the £1300 paid for the low fat content of the milk of others. Daily analyses of the mixed milk of a large dairy have shown that the fat content of the mixed milks is seldom below 3 per cent. A dairyman with a small herd of cows in certain states of lactation and nutrition may easily have a milk with less than 3 per cent. of fat and be liable to prosecution. It is impossible to safeguard this dairyman under the present standards. Even if his milk be tested directly, it may happen that on that particular day the milk passes the standard. Only by further analysis of the milk—i.e., by the determination of lactose and protein—can this dairyman be protected, for it is unlikely that protein, fat, and carbohydrate will all be below the standard at the same time. Protein may be high and carbohydrate low and vice versa; fat may be high and carbohydrate low. If all the constituents are below the limits of variation at the same time, the case is then more clearly one for prosecution.

Milk is one of the few foods which contain all three vitamins, its content in these accessory food factors depending entirely upon the food of the cow or other animal. The anti-scorbutic or C vitamin has been definitely shown to be more abundant in the milk of grass-fed cows than that of stall-fed cows. Summer milk is a better anti-scorbutic than winter milk. The same holds for the fat-soluble A vitamin. The amount of factor A in milk may be closely connected with the greater prevalence of rickets in spring (after winter feeding). The absence of the anti-neuritic or B factor in milk has been most clearly demonstrated in certain human milk. Children have been cured of beri-beri if the mother has been supplied with food containing B vitamin. All the three vitamins in milk are derived from the food of the animal and are not produced by the animal. Further, there is no connexion between chemical composition of milk and vitamin content. A milk of high fat content may be low in content of factor A. Milk from a cow on dried food does not contain C factor.

HUMAN REMAINS AS HISTORICAL DOCUMENTS.

THE opinion was at one time prevalent that we could learn no more of the origin of the British people than writers of antiquity had chosen to tell us. From the report on the Museum of the Royal College of Surgeons of England just issued by its conservator, Sir Arthur Keith, we learn that the prospect of a reliable history of the kind of people who have inhabited this country for many thousands of years past continues to improve. Only those who are familiar with the methods and industry of modern archæologists are aware of the exactness with which ancient graves and their contents can be dated. All the experience gathered by archæologists in Egypt, Mesopotamia, France, Italy, Germany, Scandinavia, and Britain is being pooled, with the result that the British archæologist obtains a clue to the dating of the various funereal customs which he comes across in the course of his explorations. From the present report, as from those of previous years, we note that the College of Surgeons' Museum is becoming a mausoleum "for such human remains as serve as historical documents." To be worth preserving human remains must be excavated with the skill that knows how to look for and how to preserve evidence of date. Anglo-Saxon cemeteries and graveyards of the Roman period are not uncommon, but very few have been explored with skill. From a Roman cemetery excavated on the property of Mrs. Clifford at Barnswood, near Gloucester, a large sample of west-country people, of the third century A.D., has just been obtained.

We learn further from the present report that the preservation of human remains of known date, which began from purely academic reasons, is likely to throw light on many problems—obviously on the prevalence of caries of the teeth, pyorrhœa, muscularity and stature of the people, but also on more obscure conditions, such as contraction of the palate and prevalence of conditions affecting the growth of bones. In the opinion of Sir Arthur Keith contraction of the palate, now affecting 40 per cent. of the modern population of English cities, is of comparatively recent origin. We are glad to note that the Scientific and Industrial Research Council has recognised the national value of the great collection of human skulls and other remains which has been built up by the Council of the College, and has given a grant to pay a research worker to compile a new and reasoned catalogue of this section of the Museum. Among other points of interest in the report may be mentioned the gift of the Onodi collection of nose specimens, and the further additions to the War Office collection of specimens illustrating war wounds and their sequelæ. We note, too, that the annual exhibition of recent additions to the Museum, formerly given in July, is henceforth to take place in October.

THE TUBERCLE BACILLUS IN PERIPHERAL BLOOD.

THE tubercle bacillus is always being hunted in some corner of the human body. Every channel of infection is explored and every secretion and excretion examined with much expenditure of carbol-fuchsin and counterstain; and yet there are still wide gaps in our knowledge of the march of the infecting organism from the point of entrance to the ultimate clinical focus of disease. Possibly the key to this "regional survey" is to be found in the circulating blood. Each successive era of experimentation seems to fasten the responsibility more definitely upon the blood, and thereby to bring tuberculosis more into line with the clinical pathology of other infective diseases. First bone and joint tuberculosis, then genito-urinary, and finally pulmonary tuberculosis become the field of our inquiry. But in spite of very reasonable grounds for hope bacteriological demonstration of the bacillus in the blood is hard to come by, except in those cases of miliary tuberculosis which are in a class apart. Shortly before the war mild excitement was caused in tuberculosis circles by the reports of Rosenberg Kurashiga[1] and others, who found bacilli in 100 per cent. of cases in the blood of both early and advanced cases of phthisis. Then followed disillusionment; others could not verify the results. Kahn[2] showed that numerous causes of error arose in artefacts; and Fraenkel[3] disposed of the 100 per cent. positive results by making inoculations of peripheral blood into guinea-pigs and finding only two positive cases out of 25; other workers obtained similar results. In an original article on this subject recently published by Distaso,[4] these results are summarised. Sixteen different investigations by various workers on 928 cases yielded 84 positive findings. Distaso, in addition, gives the results of an interesting series of experiments made by himself into the various stages of pulmonary and surgical tuberculosis (febrile and afebrile), most of which experiments yielded negative findings. A group of cases of afebrile pulmonary tuberculosis, however, gave a surprising number of positive results—9 out of 13. This group is difficult to reconcile with the findings in febrile groups, and it is unfortunate that Distaso was unable to go over this work again with re-inoculation experiments, especially as he seems to have been content with the demonstration of giant cells in his positive guinea-pigs and did not obtain tubercle bacilli. The latest report of the *Robert Koch-Stiftung*, recently received, contains an article by E. Rumpf,[5] of Hamburg, which is an exhaustive inquiry into the whole subject. Microscopic, cultural, and inoculation tests were carried out by the author, and a series of controls made upon normal people. Growth on media did not take place, whilst profession in active practice, either directly or through the Division organisation, the proposed scheme with a questionnaire, and the aggregate voting thereon be recorded and forwarded to the Division and Representative Body, together with the report on action taken.

A motion by East Hertfordshire similarly approved of the formation of any Consultative Committee on which the B.M.A. would be associated with all other bodies representing the various branches of the profession, for the purpose of negotiating with the Government.

SATURDAY, JULY 16TH.

Federation of Overseas Branches.

On a motion standing in the name of the chairman of the Organisation Committee to approve and adopt draft articles and by-laws to meet the circumstances of Overseas branches—Mr. **RUSSELL COOMBE** submitted that the position had been completely altered by the deliberations of a conference held on July 5th between overseas and Irish representatives and representatives of the Council on the question of possible federation facilities. At the chairman's request Dr. **R. H. TODD**, representing the Australian Federal Committee, spoke to this matter. Branches of the Association in Australia, he said, had to represent the profession in a very direct way, dealing as they did with independent States of the Commonwealth, and it was impossible to conduct business through the central office in London. The New South Wales branch, for example, was incorporated under the Companies Act "not for gain," had its own journal, library, and building, and was a compact organisation in itself. As a barrister he contended that such a body might legally remain a branch of the parent Association, its members being individually members of that Association. The branch as incorporated would not be entitled to act as agent of the Association or incur any liability on its behalf; the Association was therefore adequately safeguarded.

Accepting Dr. Todd's view, the representative meeting decided to scrap the scheme of de-federation already drawn up, and to accept two further recommendations of the special conference in the following form:—

> That, if possible, provision be made in the regulations of the Association to allow the Overseas branches to retain the character and status, the rights, powers, and duties of branches, although incorporated; such steps being taken as may be necessary to protect the Association from liability for any act of the incorporated body.
>
> That provision be made in the regulations of the Association for Federal Councils of the Association in the Dominions and India, consisting in either case of representatives of the branches concerned, to carry out in these countries, on behalf of the local branches collectively, the objects of the Association, and generally to have the powers and duties of the existing Federal Committees.

Affiliation with Medical and Non-Medical Bodies.

At the Representative Meeting of 1920 it was agreed that the Association should take steps to obtain further powers under its constitution whereby, without abandoning its present position as an association of individual members of the medical profession, it might become, in addition, a federation of medical bodies. The propriety of this course was raised in a long series of amendments on the agenda paper for 1921. Speaking to the first of these from Reigate Dr. **S. M. MACKENZIE** queried whether federation of any kind would strengthen the Association. Of four medical societies, numbering 2900 members, whose affiliation had been suggested, 1500 were already members of the Association. No other bodies, least of all the Royal Colleges, were demanding federation with the Association, whose real strength lay in increasing its own membership. Other speakers urged the value to the Association of its identity and individuality, and the impression left upon public men by a large individual membership with an ascertained opinion. Affiliation might, however, opportunity of thrashing out difficulties before presenting a case to the Ministry, and Dr. H. B. **BRACKENBURY** urged that the door should not be entirely closed.

Eventually, by unanimous decision, the policy was rescinded of admitting to affiliation with the Association any body other than a purely medical one, and for the present any medical body other than those Overseas branches alluded to in the preceding paragraph.

The Postal Vote.

A motion was brought forward by Cambridge and Huntingdon—

> That it be an instruction to the Council to make provision so that a postal vote on any question of policy or otherwise may be taken by any branch or division after the question has been discussed at a meeting of that branch or division, and if the members present at that meeting deem such a vote desirable.

It was argued on the one hand that the member uninstructed by being present at a discussion had no right to vote upon the things discussed; and on the other that, in a rural constituency with defective means of transport, no other means than the postal vote was available for obtaining the views of the large majority. A postal vote might diminish the personal attendance at meetings and result in those who attended losing the habit of making up their own minds; but it was also a method of interesting the whole constituency in medico-legal matters. Opinion was very evenly divided, both among representatives and members of the Council, the motion being rejected on a count by a small majority.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Second International Congress of the History of Medicine.

THIS congress, which was inaugurated in Antwerp last year, held its second meeting in Paris from July 1st to 6th; it was admirably organised and well attended, the number of delegates from the various countries exceeding those of last year. The opening ceremony was held on July 1st in the Council Hall of the Faculty of Medicine. In the absence of the Minister of Public Instruction, Mr. Coville, Director of Higher Instruction, gave a brief opening address. He was supported by Mr. Larnaude, dean of the Faculty, and vice-president of the Council of the University, and Mr. Royer, dean of the Faculty of Medicine. Prof. Jeanselme, president of the Society of the History of Medicine of France, and Prof. Ménétrier, joint-president of the congress, extended a cordial welcome to the various representatives from Great Britain, Belgium, Holland, Italy, Switzerland, Spain, Portugal, Denmark, Czecho-Slovakia, Roumania, Armenia, and Greece. At the first séance in the afternoon, papers were read by Dr. Charles Singer (London), on an MSS. attributed to Guy de Chauliac; Dr. Wickerscheimer (France), on the Miraculous Healings of Cardinal Pierre of Luxembourg (1387–1390); Dr. J. G. de Lint (Holland), on Anatomical Terms Used in Ancient Egyptian Literature; Dr. Fernandez d'Alcalde (Spain), on the Various Statutes and Seals of the Chief Ancient Universities and Seats of Medical Learning in Spain; Dr. Pasteur (France), on the Beginning of the Study of Urology in France; Dr. Leclerc, on L'Histoire du Pruneau; Dr. Sergent (France), on Medical and Pharmaceutical Caricatures in the Works of Dormier; Dr. Van Andel (Holland), on the Doctors of Molière and of the Classic Drama in Holland; Dr. Basmajain (Constantinople), on Ancient Armenian Medicine; and Dr. Ricardo Jorge (Lisbon), on Encephalitis Lethargica, Typhus and Influenza in the Historic Epidemics of the Sixteenth Century.

On the morning of July 2nd papers were given by Dr. Belohlavek, of Prague, on Inaugural Theses of the Faculty of Medicine of Prague in the Seventeenth waters, skilfully applied, do more than relieve distressing symptoms, leaving untouched the underlying causes. Hot springs are, of course, available at home, where the suggestion of a university chair in hydrology has already been mooted. Switzerland however, is, unique in providing resorts of different characters at altitudes of 4000 feet or more above sea-level. Alpine treatment obviously cannot deal with more than a tithe of the tuberculosis which arises in a densely populated lowland community; but the ease and precision with which the hygienic-dietetic treatment is carried out at such alpine resorts as Montana, Arosa, and Davos must be seen to be believed, and have their lessons for the denser lowland air. The visit included, besides the places named, the baths of Loèche, St. Moritz, and Tarasp, and the climatic stations of Lucerne and Pontresina. Some account of these will follow in due course.

VERMINOUS CONDITIONS IN LONDON: NEW LEGISLATIVE PROPOSALS.

FOLLOWING a conference of borough councils held recently in London, the London County Council has decided to make application to Parliament for amendments of their General Powers Act and the Public Health (London) Act, 1891. This is in order to secure that, in cases where persons are found to be infested with vermin, or a child is found by the local education authority to be so infested or to be in a foul or filthy condition, the premises, clothing, and other articles in use by such persons shall be liable to be compulsorily cleansed, purified, or destroyed. The attention of the Minister of Health is also to be drawn to the desirability of amending the Cleansing of Persons Act, 1897, so that it shall become the duty of each local sanitary authority to provide the necessary facilities for dealing with verminous persons. The Council will further suggest legislation empowering local authorities to inspect second-hand wearing apparel in the hands of dealers, making it an offence knowingly to deal in clothing in a verminous condition, and empowering the local authority to cleanse contaminated clothing at the cost of the dealer, or to destroy it without compensation to him.

NUTRITIVE NEEDS OF PROTOZOAL PARASITES.

ALTHOUGH the nutritive needs of bacteria have been carefully investigated, the protozoa have largely escaped notice in this respect, probably because it has been assumed that, if not actually bacteria, they required complicated chemical bodies for growth. In the current issue of the *Journal of Physiology* Dr. R. A. Peters has investigated the substances needed for the growth of a pure culture of *Colpidium colpoda*. The strain of ciliated organisms used in this research were reared from one individual, and were kept alive for about ten months, free, as far as can be ascertained, from other organisms. The original organism was obtained from a hay infusion. The organisms have a mean length of about 50 μ and one micronucleus. The technique employed is fully described; pure cultures in synthetic media were obtained from a single individual and studied for a year, at the end of which time conclusive evidence was brought forward to the effect that these cultures contained only the organisms in question. Upon a medium consisting of glass, distilled water, calcium, potassium and sodium chlorides, magnesium sulphate, and ammonium glycero-phosphate test-tube cultures have been kept going by frequent subculture without diminution of the size of the organisms. Rather better results were got by substituting glucose and ammonium lactate as nitrogen and carbon sources. By counts and measurements of size it has been found that the average maximum for growth under these conditions is 8000–10,000 organisms per c.cm. The growth curve shows three phases: (1) A rise to a maximum number, (2) a more gradual fall to (3) a plateau, during which life may continue for some time. Phases (1) and (2) last about 12 days. During phases (2) and (3) the organisms diminish in size. During phase (2) temporary rises in the number of organisms may take place. Experiments upon the omission separately of the medium constituents showed that ammonium phosphate and chloride could not be omitted from glass test-tube cultures without stopping growth. Phosphate deficiency in the medium led to apparent disintegration. The omission of potassium and magnesium in glass cultures was without effect, but in quartz test-tube cultures potassium deficiency led to failure of movement and death of the cultures. Magnesium deficiency also inhibited growth. No effect was produced by omitting the sodium, calcium, or sulphate (separately) from the medium, though it is not claimed that traces of Na, Ca, or S were altogether absent. Uranium salts also cannot be substituted for potassium salts in the growth process—a fact proving the biological value of potassium to be not solely a question of radio-activity. Amino-acids will serve as nitrogen source in place of ammonium salts. Growth has not been demonstrated on carbon sources containing less than three carbon atoms in the molecule. Glycerate is used by the growing protozoon, but not lactate or citrate. The work emanates from the Department of Biochemistry at Cambridge University, and its further development will be followed with interest.

THE RED CROSS REPORT.

A SOLID volume[1] containing over 800 foolscap pages of accounts, records, maps, and explanatory paragraphs will receive welcome and study in circles not usually attracted by such bulky publications. During the war there were few civilians of either sex or any age whose services were not offered to and accepted by the joint Red Cross societies in some capacity. The official military history of the war is awaited by the soldier or ex-soldier with keen interest, as is the medical history by the profession; but concealed in the pages of the report of the Joint War and Finance Committees of the British Red Cross and the Order of St. John will be found by the careful reader the epic of the women. Details of the nursing personnel, of the organisation of the central work rooms, and of registered work parties—a list of these covers 36 pages—and depôts, to give only examples drawn at random, record without unnecessary comment the extent to which the hitherto untrained contributed to the results achieved. The report is admirably balanced, consisting of four main sections and appendices. A preliminary note on the genesis of the Joint Committees leads on to an account of their general management, including the personnel in charge of separate departments. The various sources from which the colossal sum of £21,885,035, the total of the receipts between Oct. 20th, 1914, and June 30th, 1920, was amassed are set out clearly in tables showing that over 16½ millions in cash, and over a million in stores, were actually collected from the public. The Government grants, amounting to £681,257, were mostly capitation allowances in respect of sick and wounded men in Joint Committee hospitals. The expenditure on war work amounted to £17,340,428 and on after-care and other post-war schemes to £2,717,927, leaving a surplus on June 30th, 1920, of £1,826,680; while administration expenses were kept to the low figure of £741,725, or 3·39 per cent. of the income. The section on personnel is limited to the consideration of the paid staff sent out from headquarters. The Medical Personnel Department

CONTROL OF VENEREAL DISEASES.

The Value of Prophylaxis in Venereal Disease.

Recent laboratory and clinical research in Germany into the problems of prophylaxis of venereal disease seem largely to have centred about (1) the composition of a disinfectant which at one and the same preparation is preventive of both syphilis and gonorrhœa, (2) the length of the post-coitus interval, beyond which prophylaxis is futile, and (3) the elaboration of a fool-proof disinfectant ritual. The upshot of researches in connexion with the last problem is disappointing, although it is properly assumed that the protection of fools is desirable. Referring to his experiences in a military hospital in Roumania during the war, Dr. J. Schumacher [1] relates how soldiers initiated into the mysteries of disinfection before coitus in rooms set apart for this purpose were constantly developing gonorrhœa. He had greater success with "intelligent" persons. But even in this ill-defined class he had sometimes to register failures, and these referred to syphilis as well as gonorrhœa. This is not surprising when the elaborately detailed account of prophylactic disinfection for syphilis, as given by Dr. Schumacher, is studied. The strength of a chain is in its weakest link, and an "intelligent" pupil of Dr. Schumacher, who followed every instruction but one, developed an intra-urethral chancre because he had consistently omitted to swab out the fossa navicularis with a solution of perchloride of mercury. The gist, then, of this paper is that with suitable disinfectants and their skilled use prophylaxis is perfectly feasible, but that a disinfectant does not disinfect in the hands of an unintelligent person any more than a typewriter types in the paws of a baboon.

Reporting on their experimental studies at the bacteriological laboratory of the "Reichsgesundheitsamt," Dr. P. Manteufel and Dr. H. Zschucke[2] state that they have found mercurial salts quite as effective as silver salts in the prophylaxis of gonorrhœa, and that though an ointment containing mercurial salts may be less effective than the same strength of these salts in solution, yet by increasing the concentration of the salts in ointment form, a rapidly effective disinfectant action on gonococci can be secured. Hence their conclusion that prevention of both the principal venereal diseases can be effected by one and the same preparation, and they recommend for this purpose 0·3 per cent. sublimate in lanolin, which provides mechanical as well as chemical protection. As to the post-coitus interval, beyond which prophylaxis is futile, they stress its brevity. Siebert has shown that the Neisser-Siebert prophylactic cream may, indeed, be effective in apes six hours after infection, but Schellack has found that three minutes after intracutaneous infection with the spirochæte of recurrent fever, infection cannot be averted by washing with alcohol. Manteufel and Zschucke, experimenting with the spirochæte of recurrent fever in mice, found that within 30 minutes of infection no disinfectant was reliable. They also refer to Neisser's experiments, which showed that syphilis in apes could not be aborted when the site of infection was excised ten minutes after inoculation. Inada has also shown that five minutes after material containing Weil's spirochætes had been applied to healthy skin they had penetrated deeply enough to be beyond the control of disinfectants. These and similar experiments throw much doubt on the efficacy of late prophylaxis.

Schumacher's survey of the numerous prophylactic disinfectants which have hitherto enjoyed considerable popularity is not conducive to an easy faith in them. Metchnikoff's calomel ointment has, he says, been found quite ineffective in the prevention of syphilis by all who have tried it, and he doubts if it would ever have had much of a vogue but for the distinguished name associated with it. Probably in the rare cases in which it did achieve the desired end its success was due to the presence in the ointment of a soluble salt of mercury. As for the Neisser-Siebert ointment, it has given satisfaction in some hands, but not in others. Perhaps the failures recorded may be traced to decomposition of the constituents of this ointment, for it has been put up in metal tubes in the past, and this has meant the conversion of sublimate of mercury to metallic mercury, which is comparatively inert. Of the more complex mercury salts, hydrargyrum oxycyanatum has been extolled as being six times as potent as the sublimate, as well as being comparatively atoxic to the tissues and not being affected by contact with instruments. But Stricker has seen death follow irrigation of the urethra with this salt and, as in the case of calomel, there seems reason for the suspicion that this salt has sometimes contained impurities. Schereschewsky's quinine ointment has, in Manteufel's experience, invariably protected against syphilis, whereas he has had failures with the Neisser-Siebert ointment, and the former ranks with aqueous solutions of sublimate of mercury in efficacy. All authorities apparently agree as to the superiority of solutions over ointments as prophylactics, and the efficacy of the Neisser-Siebert ointment is enhanced if it is made up with water. Schumacher concludes that the best preventives of syphilis are a 0·1 per cent. solution of sublimate of mercury and quinine ointment: the former, in the strength indicated, is effective against gonorrhœa also, whereas the action of quinine on the gonococcus has not apparently been studied sufficiently to warrant a definite opinion on this score.

The Limitations of Wassermann's Reaction.

Two papers recently published in the Danish medical journals show again that, whether negative or positive, Wassermann's reaction should not be regarded as so infallible as to render superfluous the judgment of the skilled clinician. Under the heading "Negativ W.R.—Aktiv Syfilis," Dr. Johanne Christiansen[3] analyses the syphilis records of the Rudolph Berghs Hospital for the three-year period, 1918–1920. Of 474 patients treated in 1918, 17 gave a negative reaction, although there was clinical evidence of a secondary or tertiary outbreak. Ten of these patients had, however, undergone specific treatment at an earlier stage, but there were three who had never received specific treatment, and who, in spite of a large secondary eruption, gave a negative reaction. After giving somewhat similar figures for the two following years, Dr. Christiansen draws attention to the fact that among 12 patients, suffering from active secondary or tertiary syphilis, with no record of specific treatment, and with a negative Wassermann reaction, as many as seven were women, who were either pregnant or had just been confined.

In the second paper headed "Positiv Wassermann—Aktiv Syfilis," Dr. T. E. Hess Thaysen[4] twits the clinician for his indiscriminate faith in serological reports, and for assuming that a positive Wassermann reaction must necessarily indicate clinically active syphilis. The author recognises the great difficulties of distinguishing between latent and active syphilis, but he is convinced that there is a large proportion of cases in which, in spite of a positive Wassermann reaction and total lack of specific treatment, the disease is and remains perfectly latent. He can also establish no correlation between the intensity of this reaction and the clinical prognosis, and he justifies this view by a study of 283 cases of syphilis treated with mercury and showing a positive reaction. He gives illustrative cases to show that there may be no clinical or post-mortem evidence of syphilis in patients whose serum has presumably been capable of giving a positive Wassermann reaction for 30 years or more. He refers to Danish statistics showing that among 2598 patients attending hospital there were 57, or between 2 and 3 per cent., who gave a positive reaction, although they showed no clinical sign of syphilis and denied infection. If the patients, whose only sign of syphilis is a positive Wassermann reaction, may be contributions to the *Journal* went to the editorial staff. The appointment of an independent committee to investigate and suggest economies was turned down.

The "British Medical Journal."

A hardy annual motion that the general practitioners' needs and difficulties should receive more consideration in the *Journal* was promised sympathetic attention by the *Journal* Committee. Appreciation was expressed of the good work done by this Committee and by the editorial staff. Sir DAWSON WILLIAMS is to be presented at the annual general meeting with the Association's gold medal of merit for his distinguished services to the Association. A motion to publish in full the reports of division meetings was deemed impracticable and withdrawn.

Professional Secrecy.

A motion was submitted by Dr. R. LANGDON-DOWN, chairman of the Central Ethical Committee, to the effect—

(1) That when a medical practitioner refuses to divulge information which he has obtained in the exercise of his professional duties in such circumstances as the following: (*a*) in a Court of Law when the Court has ruled that information so obtained must be disclosed; (*b*) where it is already provided by Act of Parliament that he must do so, for instance in the notification of certain diseases; such action must be taken entirely on his own responsibility, and the Association cannot be expected to support him or protect him from consequences he may incur in so doing.

(2) That if attempts be made to add additional exceptions to the general rule of the profession as regards professional secrecy, the Association recognises that it will be necessary, after consideration (i.) to resist by all lawful means any such encroachment, and (ii.) where such encroachment is attempted to accord support by any means in the power of the Association to any individual practitioner who may be assailed through such new encroachment

In the discussion that followed it became at once apparent that representatives were prepared to go much further than a year ago, and that the Central Ethical Committee's motion would not suffice them. In his amendment from Birmingham Central, Dr. H. G. DAIN pointed out that it by no means necessarily served the public interest for a doctor to disclose professional secrets on the instruction of a judge. Every individual member of the public had no doubt that *his* doctor ought, under no circumstances, to tell anything about him. Statute recognised no right of refusal to give evidence, even for the lawyer and the priest, but common law admitted privilege for the lawyer, and the priest was never asked. Many States of America, France, and New Zealand protected the doctor who refused in civil cases to violate his patient's confidence. Let the doctor refuse in the English court and take the consequence with the Association behind him; no judge had yet committed a doctor for contempt under these circumstances. After prolonged and searching discussion, in which the solicitor supplied a telling illustration of the class of case in which a medical man may help the ends of justice by supplying information, the following amendment was put and carried with not more than a dozen dissentients:—

That the Association use all its power to support a member of the Association who refuses to divulge, without the patient's consent, information obtained in the exercise of his professional duties, except when it is already provided by Act of Parliament that he must do so.

Not having been presented with the statutory two months' notice, this amendment, now passed as a substantive resolution, cannot become the accepted policy of the Association until the next representative meeting, but it will appear as such on the agenda next year, and in the meantime be a recommendation to this effect to the Council.

Proposed Central Medical Committee.

On a motion standing in the name of the chairman of Council to approve the section of the annual report setting up a Central Medical Committee representative of the profession as a whole to consult with the Minister of Health on questions of policy affecting the profession, Dr. BOLAM opened by admitting that the matter was in abeyance. Action was initiated owing to some remarks of Dr. Addison, late Minister of Health, substantially as follows:—

"On several occasions I have said in public 'If you want us to consult you, get busy and set up machinery whereby you can readily be consulted.' I quite agree as to the reasonableness of consultation in the formative stages regarding regulations or conditions, or general principles, if some machinery for consultation were available, but I will not consult half a dozen different bodies, each claiming to represent the profession. No body of medical men is more competent than those before me to-day to state a case for the profession, and I should be very glad to see them in consultation. I am speaking now, of course, of consultation with an exterior body, in respect of the profession generally. I am leaving out of account for the moment the Consultative Council, which is now a part of the machinery of the Ministry. As soon as practicable, I, or an officer acting on my behalf, will be willing to discuss the general principles with some body representing the profession. I can imagine no organisation better qualified than the British Medical Association to get together a representative body, but I repeat that I am not going to make an agreement of this kind with a number of different bodies each claiming to be representative."

At the time of issue of the annual report the position was that the Society of Medical Officers of Health, the Poor-law Medical Officers' Association, and the Association of Certifying Factory Surgeons had agreed to coöperate in the formation of a central medical committee; the Medical Women's Federation was discussing the matter at its next Council meeting; and the Medico-Psychological Association had stated that it would be glad to coöperate with the British Medical Association through the Federation of Medical and Allied Societies in all matters and questions to be considered by the Ministry of Health.

A new Minister of Health was now in office, and the Association, Dr. Bolam said, was awaiting the reopening of the whole question. In the discussion which followed it was suggested that it was childish to ignore the Medico-Political Union in getting the collective medical opinion of the country. Lord DAWSON thought the best way out of a thorny path was to leave matters in the hands of the Council to explore, leaving out of account for the moment the Consultative Council of the Ministry of Health, which had not yet matured. He paid a tribute in passing to the perspicacity, foresight, and sympathy of Dr. Addison. This Committee was in the nature of a medical charter to be jealously guarded; it had been given the right to initiate advice. Maybe its methods of selection might and could be improved. Dr. H. B. BRACKENBURY described the Consultative Council as a check upon bureaucracy, and as a useful agent for the Association to uphold. "You will," he said, "never get a united representation of the medical profession at the Ministry of Health; there will always be small minorities on every question; but the Association was in and by itself sufficient to represent the medical profession."

It was finally agreed to remit the whole matter to the Council for its consideration, along with the following motions standing in the name of the divisions noted:—

Motion by Portsmouth: That the Representative Body is of opinion that the collective opinion of the medical profession can be adequately and truly expressed to the Minister of Health only through a body elected directly by the profession for that purpose, such body to have the power, if thought advisable, to coöpt for any special purpose representatives of the medical profession not exceeding one-third of the total number of the Committee.

Motion by Portsmouth: That this election should be organised and conducted by the British Medical Association.

Motion by Sheffield: That this meeting endorses the view expressed by Dr. Addison, as Minister of Health, that in taking action to bring together a body representative of the whole profession for the purpose of consultation by the Government, the British Medical Association is the most suitable body to take steps for its organisation.

Motion by Brighton: That any scheme placed before the Minister of Health by which it is considered the collective opinion of the members of the medical profession in active practice can be obtained on questions of policy should be submitted to and approved by them; that it be an instruction to the Council to submit to all members of the medical

Its first notable recommendation in this respect (par. 34) is that certain provisions of the Health Acts, 1919, which enable powers and duties of the Minister of Pensions with respect to the health of disabled officers and men to be transferred to the Minister of Health, should be reconsidered with a view to their repeal. It can hardly be wrong thus to avoid the possible overlapping of functions, and to retain the care of pensioners requiring continued treatment in the hands of the Minister primarily responsible for their welfare.

As to the new regional arrangements proposed, we note in the portion of the report devoted to this subject a recommendation that the new regional offices should be obliged to deal carefully with complaints, and that awarding and medical officers should be instructed to explain briefly, in answer to queries, the grounds of a decision given. This imposes a certain amount of additional trouble on the medical officer, but, so far as such instruction can be complied with, it may promote smoothness of working and the contented acceptance of decisions. A statement of the grounds of a decision on a medical matter will, however, always be primarily of interest to the medical advisers of the pensioner whose opinion it may overrule, and the knowledge that it will have to be given will be a valuable protection to the pensioner. Paragraphs 137–141 deal with means for rendering the medical history of a pensioner more readily available as an aid to his efficient treatment.

The Organisation of Medical Services.

Part VI. of the Report is devoted to "Medical Services," dealing, firstly, with their cost, and, secondly, with their organisation and duties. Their approximate total cost for the year ending March 31st, 1921, is given as £9,187,271; of this, however, the supply of artificial limbs and surgical appliances, and the travelling expenses of patients, account for over £1,100,000. With regard to the duties to be performed by medical officers, the performance of these by regional rather than by headquarters officers is advised, and a strong recommendation is made as to relieving medical officers of clerical duties that can be performed by a lay staff (par. 335). The consideration of the work of the medical boards occupies several pages, and suggestions are made having to a large extent the object of preventing complaints and securing the pensioner's understanding of and acquiescence in the award to be made. The reducing of the personnel of medical re-survey boards is advised as a means for securing attendance only of those necessary, with the consequent quicker despatch of business. The continued use of civil hospitals for in-patient treatment is recommended (par. 352). It is found that there has been no delay in admission to hospitals, except unavoidably in neurological cases (par. 353). With regard to the staffing of the Ministry's hospitals, recommendations are made with a view to economy, and as to details affecting the discharge and admission of patients. The establishment of a clearing-house at regional headquarters for dealing with questions of in-patient admission to hospitals (par. 359) is suggested. With reference to the treatment of pensioner out-patients, the number of clinics established by the Ministry amounts to 140. This number only has been sanctioned by the Treasury, and the proposal of the Ministry that an increase to 250 should be allowed is endorsed by the Committee, with further suggestions as to the use to be made of the clinics.

The Care of Mental Cases.

The care of certified mental cases is one of the duties of the Minister of Pensions, and among the officers appointed by him is a medical inspector (neurological), who, with a member of the Board of Control, is employed in carrying out necessary investigation as to the treatment of service patients in institutions. Less than one-fourth of the asylums made use of having up to now been visited, the Committee ma[illegible] strong recommendation that the process of i[illegible] should be expedited. The setting up of mental hospitals for certified cases by the Ministry is not recommended, for the reason that they would be few in number and often at too great a distance for the patients' relatives to visit them.

We note that a certain amount of apprehension is expressed by the Committee that the welfare of the tuberculous is not adequately cared for, and that a warning recommendation is thought necessary as to the better provision for them of sanatorium treatment (par. 378). More supervision over the provision and standard of dental treatment is also urged. The establishment of additional limb-fitting centres is also advised.

"The Officers' Friend."

In Part VII. officers' pensions and medical treatment are discussed, the general result being that the present administration at headquarters is considered satisfactory, and will, subject to suggestions as to details, the arrangements, so far as they depend upon the coöperation of the medical profession, be continued. In conclusion, it may be noted that under the heading "Special Assistance" the report testifies to the useful work done at the headquarters of the Ministry by the branch known as the "Officers' Friend." This is performed by a small staff of ex-officers, who assist officers and their relatives in regard to their claims, and explain the regulations to them. Medical officers suffering from the effects of their war service, and the widows and dependents of dead officers, if not satisfied that they have fully understood their right to pension and other assistance from the Ministry, should not fail to consult the "Officers' Friend."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Meeting of Council.

THE quarterly Council meeting was held on July 11th, Sir Anthony Bowlby, the President, in the chair. Mr. H. J. Waring, Mr. F. F. Burghard, Mr. W. Thelwall Thomas, and Mr. C. H. Fagge were introduced, and took their seats on the Council. A report was read from the Board of Examiners in Dental Surgery respecting candidates found qualified for the Licence in Dental Surgery, and licences were granted to 53 candidates named in the report. A report was read from Mr. F. G. Hallett, secretary to the Conjoint Examining Board of England, respecting candidates found qualified for the Diploma in Public Health, and it was resolved that diplomas be granted jointly with the Royal College of Physicians of London to 23 candidates mentioned in the report. A report was read from Mr. Hallett respecting candidates found qualified for the Diploma in Psychological Medicine, and it was resolved that diplomas be granted jointly with the Royal College of Physicians to six candidates mentioned in the report. It was resolved that the best thanks of the Council be given to the President of the American Museum of Natural History, New York, for presenting a plaster cast of the Chapelle skull and models of Dr. J. H. McGregor's reconstruction of the Gibraltar skull and brain cast: and also to Lieut.-Colonel R. H. Elliot for presenting a collection of 46 specimens illustrating rare pathological conditions of the eye. A report was read from the Committee of Medical Education and Examination, and the Council expressed their general approval of the proposed course of study and examination, and referred the report to the Committee of Management to consider. A report was read from the Committee on additional examinations in Ophthalmology and Oto-Rhino-Laryngology, which recommended that candidates for the examination in ophthalmology must be Fellows of the Royal College of Surgeons, and that they must produce evidence of having devoted, after becoming qualified, at least two years to the study of ophthalmology as a clinical assistant, house surgeon, or registrar at a recognised institution. The report was referred to Mr. Burghard and Mr. R. Johnson, in consultation with Mr. J. B. Lawford, Mr. E. Treacher Collins, and Mr. J. H. Fisher, to prepare for the approval of the Council the regulations for candidates for the proposed examination in ophthalmology. The President reported that in response to an invitation to the College to nominate a member of the "Hospitals Commission" recommended in the report of Lord Cave's Committee, he had nominated Sir George Makins to act in this capacity. The Council elected Sir Anthony Bowlby as President for the ensuing year, and Sir Charles Ballance and Sir D'Arcy Power Vice-Presidents for the same period.

Century; Dr. Brunon (France), on the Catalogue of the Museum of the Hotel de Dieu at Rouen; Dr. Cabanès (France), on the History of Psycho-Pathology; Dr. Blanchet (France), on the History of Medicine—Dissection and Vivisection; Dr. Dubreuil-Chambardel (France), on the Infirmaries of the Abbeys in the Eleventh Century, and the Disease of St. Sylvain in the Eleventh Century; Dr. Le Gendre (France), on the Life of Bouchard when a student in Lyons; Prof. Ménétrier, on Medical Anecdotes of the Sixteenth Century after the Contes d'Eutrapel; Dr. Sigerist (Zurich), on Conrad Heingarter, of Zurich, and Astrological Medicine in the Fifteenth Century; and Dr. Villaret, on the Origin of Intravenous Injection. On Sunday, July 3rd, at St. Germain-en-Laye, Mr. Solomon Reinach gave an interesting address in the National Museum of Antiquities on the Gallo-Roman remains.

At the morning session on July 4th papers were read by Dr. Bérillon (France), on Le Dormeur de la Hollande; Dr. Bertrand (France), on History of the Plague in Antwerp; Mr. Buchet (France), on the History of the Druggist; Dr. Delaunay (France), on Travelling Doctors in the Marne under the ancient régime; Dr. Dorveaux (France), on the Surgeons of Metz; and Prof. Laignel-Lavastine (who with Dr. Fosseyeux was joint secretary to the congress), on Psychiatry in France in the Eighteenth Century. On July 5th, in the morning, Prof. Guiart (France) gave a paper on Obstetrics in Ancient Egypt, illustrated by lantern slides; Prof. Schrutz (Prague), on Magister Gallus and Czech Medicine in the Fourteenth Century; Mr. C. J. S. Thompson (London) and Dr. Van Gils (Holland) gave lectures, illustrated by lantern slides, on the Pomander as a Link in the History of Preventive Medicine and on Medical Iconography respectively. In the afternoon the following papers were read: Prof. Jeanselme, Dietary in the Convents and Hospitals in Byzantine Times; Dr. Semelaigne, MSS. of Hiriel; Dr. Girard, Marcel Duval and the School of Naval Medicine in Antwerp (1810–1814). On July 6th, in the morning, papers were delivered by Prof. Hervé (France), on Une Expérience d'ingestion volontaire du virus rabique; Dr. Meige (France), on Some Rites of Divining in Antiquity; Dr. Adamidi (Geneva), on a Short History of the French Hospitals in Constantinople and Cairo in connexion with the French Missions to the East; Dr. Van Schevensteen (Belgium), on the Plants used in the Treatment of Eye Diseases; Dr. Fosseyeux (France), on Medicine in Italy in the Time of Dante; Mr. Guitard (France), on the Ancient Statutes of the Apothecaries of Toulouse; Dr. Lecène (France), on a Note on Surgery in Ancient Greece; Dr. Olivier (France), on Medical Ex Libris; Dr. Raymond Neveu (France), on Recent Excavations at the Temple of Æsculapius at Epidauris; Dr. Rambaud (France), on the Organisation of the Faculty of Medicine in Poitiers in the Sixteenth and Seventeenth Centuries; Mr. Van Schoor (Belgium), on the Oath of the Apothecaries; and Dr. Bouvet (France), on Medical and Pharmaceutical Advertisements in Journals of the Seventeenth and Eighteenth Centuries.

The museum of historical medical objects, loaned by various institutions and members, was arranged in a large room in the school of medicine. It included a fine collection of medical coins, medals, and plaquettes lent by Prof. Gilbert and Dr. Desnos, and a large collection of surgical instruments of the eighteenth and nineteenth centuries was exhibited by the Faculty of Medicine of Paris. Dr. Guelliot lent some interesting Roman bronze surgical instruments and antiquities excavated at Rheims, and Dr. Harmonic lent his fine collection of medical antiquities. This comprised some interesting French microscopes of the eighteenth century; bronze mortars of the sixteenth and seventeenth centuries; Greco-Roman surgical instruments; Persian anatomical drawings, sixteenth century; some curious specula of the sixteenth and seventeenth centuries; artificial limbs of iron as figured by Ambroise Paré, sixteenth century; ancient appliances for reducing fractures, seventeenth century; two accouchement chairs, one of which was a portable contrivance for use of the "sage-femme." Prof. Laignel-Lavastine lent a medallion of the Baron Larrey, and some curious wooden urinals used for infants. An anatomical figure or mannikin of ivory and an amulet of St. Gorgan was lent by the École de Médecine of Rouen. Dr. Coulomb exhibited his interesting collection of artificial eyes, consisting of the eyes inserted in ancient Egyptian mummy cases, Utchat eyes in faience, and the artificial eye of more recent times. The Administration Générale de l'Assistance Publique exhibited a number of prints, and the seal and portrait of Baudeloque. A collection of old pharmacy jars, mortars, old drugs and books were lent by the Pharmacie Centrale de France. Dr. Guillon lent an endoscope of Desormeaux of 1852, and Dr. Berillon exhibited a large collection of charms and amulets. These, together with many other objects, formed a museum of considerable interest, and one which attracted numerous visitors. During the congress visits were paid to various hospitals, museums, and places of interest in the neighbourhood of Paris, and various receptions were given to the members, who also, by invitation of Dr. Henry de Rothschild, attended a special performance of "La Caducée."[1] At the closing session, held in the afternoon of July 6th, it was decided that the next meeting of the congress should be held in London in 1922.

Report of the Académie de Médecine upon Protection against Radiation.

The report of the Commission du Radium (sur les dangers des radiations pénétrantes et les moyens de les éviter) adopted by the Académie de Médecine contains a carefully complied résumé of the risks involved in the manipulations of radium and of the more penetrating kinds of X rays. The attitude of the Commission towards these dangers is identical with that of the committee in England whose preliminary report has recently appeared in THE LANCET; it is held that the dangers may be avoided by the adoption of well recognised precautions. Radiological practice in France is not entirely without legal restrictions, in many ways to its benefit, and the question of adequate space where work of this kind is carried out is one of great importance, not only because of the rapidity with which the radiation diminishes with the distance from the source (the inverse square law), but also because adequate ventilation in small rooms is very difficult to arrange. The law in France requires a minimum of 4 by 5 metres for radiological rooms. The report is a well balanced exposition, neither disregarding dangers which exist nor adopting an attitude tending to exaggerate them. It reminds the reader that our normal habitat is one which is not free of penetrating radiation, and by a few well-chosen examples it shows that a reliable basis of security for all radiologists is afforded by the rational and consistent use of protective devices.

Action of Bismuth Compound on Syphilis.

At a recent meeting of the Académie des Science, Mr. E. Roux, director of the Pasteur Institute, communicated the results of a series of researches made by MM. C. Levaditi and R. Sazerac at the Pasteur Institute. The researches consisted of the study of the effects of intravenous and hypodermic injections of solutions of tartrobismuthate of potassium and sodium into rabbits into which human syphilitic virus had been injected previously; the action of the same chemical compound was also tried in the case of trypanosomiasis nagana in the guinea-pig. The report points out that the results obtained have encouraged the authors to treat with this tartrobismuthate patients suffering from syphilis, and that they claim to have observed that the spirochætes disappeared from chancres and papules after one injection.

observed in the case of superficial lesions. Combined infections, if of sufficient importance, can simultaneously be cleared up by the use of appropriate autogenous vaccines.

Under treatment on such lines patients can be seen to exhibit rapid improvement, and can be treated in large numbers, in their own homes, at a vastly reduced cost with correspondingly enhanced chances of recovery. Many other observers at home and abroad, working on these lines, which were introduced in their original form by Dr. D. Curle of Glasgow in 1912, have attained excellent results.

I am, Sir, yours faithfully,
J. F. HALLS DALLY.
Harley-street, W., July 18th, 1921.

THE ULTRA-MICROSCOPIC VIRUSES.

To the Editor of THE LANCET.

SIR,—I should like to call some attention to the numerous papers on the so-called phénomène de d'Herelle which are creating so much interest in the French school, and which are at present being published in the French scientific journals. May I point out that the work of d'Herelle is little more than a confirmation of my work which was published in THE LANCET of Dec. 4th, 1915, under the title of "An Investigation on the Nature of Ultra-Microscopic Viruses." At the time I realised the significance of the results, as may be seen by a reference to my paper. Unfortunately, although I discussed the results in this country, and in Salonika, during the war, the civil and military authorities did not appear to appreciate their significance or the possibility of their relation to the problems of infection and immunity. As no one in this country has taken much interest in the work, it has rested with the French school to repeat the investigation and to monopolise this field of research. It is only recently that Bordet and one or two other workers have recognised the priority of my work.

I am, Sir, yours faithfully,
F. W. TWORT.
The Brown Institution, London, July 18th, 1921.

ON DEATH FROM RESPIRATORY AND NOT FROM CARDIAC FAILURE.

To the Editor of THE LANCET.

SIR,—The recent correspondence under this heading in THE LANCET of July 2nd and 9th is doubtless of interest to anyone who has had any appreciable experience in the treatment of cerebro-spinal fever. In subacute and chronic cases of this disease death from respiratory failure was more frequent than otherwise. It generally resulted soon after lumbar puncture failed to relieve the symptoms. Autopsy, when obtainable, invariably revealed acute hydrocephalus and signs of acute inflammation at the base of the brain, particularly adhesions and purulent deposits between the cerebellum and medulla. In some cases even the free passage of the cerebro-spinal fluid through the ventricles appeared to be obstructed by large purulent clots.

In the case of one patient artificial respiration was kept up for over four hours, and even then a flickering though slow and irregular pulsation could be felt at the wrist. For over two hours the pulse was quite strong and regular. In another case of tuberculous meningitis artificial respiration carried on for one and a half hours was followed by temporary recovery lasting a good part of a week. Early surgical treatment as soon as lumbar puncture fails offers the only prospect of success in the cerebro-spinal fever cases, but, unfortunately, results even then are not very promising. The pathological conditions already present are very often beyond repair.

I am, Sir, yours faithfully,
D. H. C. GIVEN, M.D., D.P.H.,
Surgeon-Commander, R.N.
1921.

THE BRUSSELS M.D. FOR BRITISH GRADUATES.

To the Editor of THE LANCET.

SIR,—I have received the following official notice: "There will be no more M.D. Brussels examinations held and diplomas for same delivered by the University of Brussels." As the privilege of proceeding to the M.D. Brux. has been enjoyed by British and Colonial candidates for the last 40 years, there is good reason for asking the authorities of the University of Brussels to reconsider their decision. I am therefore preparing a Petition to the University, and should be glad if every medical graduate of the University in all parts of the British Empire would communicate with me, so that I may send in as many names as possible.

I am, Sir, yours faithfully,
ARTHUR HAYDON, M.D. Brux.,
Hon. Sec., Brussels Medical Graduates' Association.
41, Buckland-crescent, London, N.W. 3, July 16th, 1921.

Medical News.

UNIVERSITY OF MANCHESTER.—The following appointments have been made: Senior Lecturer in Physics, Mr. E. C. S. Dickson, B.A. Camb., Ph.D. Bonn; Lecturer in Systematic Surgery and Assistant to Professor of Systematic Surgery, Mr. W. H. Hey, M.B., Ch.B. Manch., F.R.C.S., L.R.C.P.; Lecturer in Clinical Surgery and Assistant to Professor of Clinical Surgery, Mr. Charles Roberts, M.B., B.S. Lond., F.R.C.S.; Lecturer in Pathology, Mr. Arnold Renshaw, M.D., B.S. Lond., F.R.C.P.; Lecturer in Bacteriology, Mr. J. H. Dible, M.B., Ch.B. Glasg., M.R.C.P. The following awards have been made: Platt Physiological Scholarship, S. L. Mucklow; Dauntesey Medical Entrance Scholarships, F. H. Smirk (First), H. B. Kitson (Second); Dumville Surgical Prize, H. L. Sheehan; Platt Biological Exhibition, Ethel Bunting; John Dalton Natural History Prize, divided between O. D. Hunt and William Leach.

A graduation ceremonial was held on July 14th, at which most of the degrees conferred were in medicine and surgery. Sir Henry Miers, the Vice-Chancellor, in addressing the new graduates, characterised the studies of medical students as the longest and most responsible and exacting of University courses; and it seemed rather hard to the medical student that something was always being added to the course, while nothing was ever taken away. One remedy seemed to be to throw more and more of the preliminary work back upon school life. Nowhere in this country was there a larger amount of material available for clinical experience and research than in Manchester. The doctor had not only to be a skilful and a learned man, but he had also to be a wise man. Perhaps in no other profession was a man or woman called upon to exercise more responsibility and to give more help and advice outside his own work. The University aimed at equipping students for that kind of life. It encouraged the wider spirit of sympathy and interest in all that made up human life, and, above all, it cultivated the spirit of inquiry which was at the basis of all progress.

The Diploma in Public Health has been awarded to the following practitioners: Allan Barrett, K. D. Bean, Mary Boullen, G. F. Bowman, J. W. Chadwick, William Edge, Douglas Fisher, Austin Furniss, Ernest Jones, W. H. Kauntze, Emily M. Peach, A. W. Ritchie, W. R. N. Smithard, R. J. Staley, and William Stott.

At examinations held in July the folowing candidates were successful:—

FINAL M.B. AND CH.B. EXAMINATION.

S. Almond, *§G. V. Ashcroft, Martha F. Barritt, E. C. Berg, Nancy E. Bleakley, ‡Muriel Coope, T. E. Coope, Eugenia [illegible], R. A. Cooper, S. W. Drinkwater, Winifred M. Edgehill, T. M. Fisher, Kathleen M. Fullerton-Bailey, E. Gleave, W. H. Gratrix, Ruth Hill, C. D. Hough, Violet M. [illegible], R. R. Lane, Eva G. le Messurier-Kneebone, C. Nelson, L. S. Potter, W. L. Powell, Harriet R. Reid, Annie Rothwell, *§ †§H. L. Sheehan, *†‡Margaret Single, H. Stafford, S. Wand, S. Waterworth, and R. Williams.

* Awarded distinction in Medicine. † Awarded distinction in Surgery. ‡ Awarded distinction in Obstetrics. § Awarded First-Class Honours. ‖ Awarded Second-Class Honours.

DIPLOMA IN DENTISTRY.

Final Examination.—R. Ackers, D. M. Barnes, Elizabeth Benson, C. C. Breakell, P. A. Gardner, W. Garstang, H. F. Kirkbride, J. C. Knowles, H. Laslett, R. A. Lewty, J. E. Spedding, G. Stirling, R. M. Timperley, J. E. Thornton, Gracie Walker-Anderson, S. Whitworth, and W. R. Williams.

assumed to be syphilitic, the remarkable conclusion can be drawn that they represent between one quarter and one-fifth of all the syphilitic cases among the 2598 just mentioned. In a group of 120 cases of syphilis observed by Dr. Thaysen, only 46 showed clinical evidence of syphilis—i.e., 62 per cent. were in what he defines as the late stage of latency. Of this majority of 74 latent cases, as many as 59 gave a positive W.R. Dr. Thaysen gives numerous other statistics, from which he concludes that a positive W.R. in the late stage of latency does not necessarily foreshadow a recurrence of active disease. In the majority of cases in which the first infection dates back 25 years or more, and in which there has been no clinical sign of active syphilis, there is good reason for assuming that the disease will probably continue to remain clinically inactive. The moral of this paper is not that serological evidence should be ignored, but that the clinician should not allow himself to be hustled into therapeutic meddling by a serological report unsubstantiated by the patient's present state and clinical record.

The Cause of Relapses of Gonorrhœa in Children.

In two recent papers, Dr. Edith Valentin has added to our knowledge of gonorrhœa in childhood, and one important feature of her research is the demonstration of the frequency with which gonorrhœa of the female genitals in childhood is complicated by gonorrhœa of the rectum. She sees in this disease of the rectum a reservoir of infection which determines recurrence of gonorrhœa in the female genitals weeks, and even months, after they have been effectively sterilised by antiseptic treatment. In her first paper[5] she deals with the 161 girls admitted between July 15th, 1919, and Dec. 1st, 1920, to a convalescent home in Berlin for the subjects of infantile gonorrhœa. Her first task was to determine the frequency with which the parts adjoining the vulva were affected. The urethra invariably contained gonococci, and they were also found in the catheter urine of 30 out of 44 consecutive cases examined for gonorrhœal cystitis. But for lack of histological and cystoscopic examination of the bladder, it was doubtful whether the gonococci found in the urine had established themselves in the walls of the bladder or were only incidental visitors displaced from the urethra into the bladder. The cervix was also examined for gonococci, and they were found here in 7 out of 17 cases of acute gonorrhœa. In 24 cases of chronic gonorrhœa and in 13 cases of gonorrhœa which had been suppressed by local treatment, the cervix was not once found to harbour the gonococcus. The examination of the rectum for gonococci being complicated by pitfalls for the unwary, the precaution was taken first to examine the rectal flora of about 100 healthy infants. In the 8 or 10 cases in which pus cells as well as bacteria were found, some definite reason for this evidence of inflammation, such as the presence of oxyuris, was always demonstrable. In a series of 94 children, suffering from recent or chronic gonorrhœa, all, with only two exceptions, harboured the gonococcus in the rectum. The abundance of leucocytes suggested that the gonococci were not leading an innocent, saprophytic existence in the rectum, but were provoking an inflammatory reaction, although there were no symptoms referable to this region. Dr. Valentin concludes this paper with the opinion that, in the absence of oxyuris, the presence of pus cells in the rectum of a child suffering from gonorrhœa of the vulva is proof of gonorrhœa of the rectum.

In her second paper[6] she urges the extension of local treatment for gonorrhœal vulvo-vaginitis to the rectum if the physician wants to eliminate the most frequent cause of relapse. In 61 cases which relapsed 6 to 21 weeks after the vulvo-vaginitis had apparently been cured, she invariably found gonococci persisting in the rectum. In none of these cases was there any sign of bartholinitis; the catheter urine did not contain gonococci, and the cervix was also gonococcus-free. Thus the only source of reinfection seemed to be the rectum.

THE MACHINERY OF PENSION ADMINISTRATION.

THE War Pensions Bill, introduced in the House of Commons by Mr. Ian Macpherson, was read a second time without a division only three days after the publication of the Report of the Departmental Committee of Inquiry[1] upon which it is founded. This was quick work, giving no time for persons affected to consider and discuss radical changes of some importance. There will, however, no doubt be opportunity for criticism, and perhaps amendment, when the House considers the Bill in Committee. As it stands, it renders effective those portions of the Committee's report which required legislation to bring them into operation, and leaves matters which are questions of departmental administration for the Ministry of Pensions to deal with.

New War Pensions Committees.

It provides mainly for new and fewer War Pensions Committees, subject to centralised supervision, and exercising jurisdiction over rearranged and wider areas than did the numerous voluntary committees in existence hitherto, the new bodies being appointed by the Minister of Pensions from classes of interested persons specified in the Bill. It is to be hoped that the Minister will have at his disposal such information as will enable him to appoint wisely. The chief provision of the Bill directly affecting medical men engaged in the administration of war pensions is contained in Clause 3 (3) (*b*). Clause 3 provides for the making of final awards in the case of officers and men already drawing pensions, and gives a right of appeal against such awards to a Pensions Appeal Tribunal. A second medical member will take the place of the legal member of former tribunals. These, Mr. Macpherson stated, will now consist of two medical men, an ex-service man, and an officer. The strengthening of the medical element in such tribunals is obviously a sensible and natural change, when it is remembered that the chief, if not the only, question in assessing the permanent pension to be awarded will be the present and probable future extent of the incapacity in respect of which the pension is granted.

The important question of permanent pensions has received prompt attention in the new Bill, following upon a strong recommendation by the Committee that it should be considered without delay, and in particular that about 100,000 outstanding questions of "entitlement" should be finally disposed of. The Bill proposes that the case of every officer and man "shall, with a view to making a final award, be taken into consideration not later than four years after his discharge from the service or after the first award of a pension to him, as may be prescribed by regulations." Provision is made for appeal within a year by a claimant dissatisfied with such final award on the ground that it ought not to have been made or that the proper amount has not been awarded.

Economy in Administration.

The Departmental Committee was appointed "to inquire into the system and methods of administration of the Ministry of Pensions, with special reference to the working of the regional and local committee systems, and the existing arrangements for the issue of pensions." With such a reference it has naturally devoted a large part of its efforts to recommendations of reorganisation that will bring about economy in administration, always keeping in view the efficiency of the department for the performance of its functions. In the Bill referred to "pension" means "any pension, grant, gratuity or allowance in respect of disablement," under any of the warrants or orders administered by the Minister, and the efficiency of pension administration on its medical side has received full consideration in the Committee's report.

to the institution of a diploma in nursing, and regulations have been framed to this end. The standard of general education of the candidates required will be high, the hospital training must extend over a period of four years, and before candidates are accepted from the nursing staff of any hospital the University must be satisfied that the training given is adequate. In the first instance the candidates will be probably drawn exclusively from the nursing staff of the General Infirmary at Leeds. The regulations are, indeed, framed upon the course of training which has been in force there for some years, but it is not intended by the University to exclude candidates from elsewhere, though some residence and some attendance on lectures delivered at the University is required from all candidates. The hospital certificate of training given to nurses who have passed through their training satisfactorily will, of course, continue; the diploma carries the nurse a step further, and it is intended that it shall rank as a definite mark of distinction. The regulations for the diploma, for which a fee of £5 is required, will be furnished on application to the University.

THE LATE DR. JAMES SMART, OF ABERDEEN.—The death took place suddenly on July 13th, while on a holiday visit at Kyles Hydro, Rothesay, of Dr. James Smart, a well-known general practitioner in Aberdeen. Dr. Smart, who was 48 years of age, was a native of Oldmachar. He was educated at Elgin and Aberdeen University, where he graduated M.A. in 1894 and M.B., Ch.B. in 1899. He had been in practice in Aberdeen for 22 years. On the outbreak of war he was appointed registrar at the 1st Scottish General Hospital with the rank of captain. Soon afterwards he was promoted to the rank of major, and in 1916, when Lieut.-Colonel Mitchell, the O.C. of the hospital left for service overseas, Major Smart succeeded him in command with the rank of lieutenant-colonel. In 1918 he took over temporarily the command of Bangor War Hospital, and later proceeded to London, where he commanded the 4th General Hospital. A cheerful, courteous, and many-sided man, Dr. Smart's untimely ending has come as a shock to numerous friends.

HOSPITAL CONDITIONS IN BRISTOL.—As in other cities, so also in Bristol, the voluntary hospitals are in financial straits. The Royal Infirmary is issuing an appeal which states that there is a debt of £70,000 to be paid off, and suggests that this might very properly be regarded as a war memorial, since it was in the infirmary buildings that much of the work of the 2nd Southern General Hospital was carried on. As was recently stated in our columns Mr. H. H. Wills, the president of the hospital, has given £100,000 in securities to the infirmary, but this is intended as a permanent endowment and not as an extinction of accumulated debt. The plans for collection of payments from patients have come into operation, both at the Royal Infirmary and at the General Hospital, during the past week, and this has already called forth from one large firm—that of Messrs. J. S. Fry and Sons—a double response which may well furnish a valuable precedent not only in Bristol but elsewhere. In the first place, the directors undertook to pay the standard charge—£1 1s. per week—for any employee admitted to either hospital for in-patient treatment. Secondly, the employees have now formulated a scheme for the deduction of 2*d.* per week from their wages in the place of the present voluntary contribution of 1*d.* per week. The sum thus collected is to be devoted in part to a general contribution to the funds of the hospitals, in part to an amplification of the directors' scheme. This step on the part of the employees is entirely spontaneous, and is most encouraging in view of the fears expressed as to the probable falling-off in workpeople's contributions when a scheme of payment by patients was introduced.

GUY'S HOSPITAL: ANNUAL REPORT.—The report for the year ended Dec. 31st, 1920, shows the number of patients who received treatment in the wards during that period to be 9309, and the number of separate visits of out-patients to be 496,466. The call upon the resources of the hospital was greater than ever; no wards were closed, no facilities for treatment were withdrawn, and the whole services of the institution were fully employed, but the great costs of working, in spite of strict economy, render the future prospect very serious. The expenditure of the hospital was £166,203, against £73,574 in 1913. A reduction in the average stay in hospital from 23·6 to 22 days made it possible to pass through the wards over 500 patients more than in the previous year. The mortality-rate in the wards was 7·2 per cent. The special appeal for further support, addressed to firms and individuals having premises near the hospital, met with an encouraging response; many regular subscribers had increased their benefactions, and nearly 700 new contributors had subscribed, but the income and expenditure account showed a loss for the year of £21,791. The [illegible]rs felt that the institution of a compulsory monetary charge to patients would be at variance with the expressed desire of the Founder of the hospital and inconsistent with the spirit of the charity as hitherto maintained; but they saw little objection to asking patients to contribute voluntarily according to their means. Roughly one in three had responded to the appeal now made to each individual patient; a proportion of those who did not contribute wrote explaining that unemployment, sickness, &c., prevented them from doing so. Support in the form of endowment is now greatly needed for the medical school; further, the Governors invite subscriptions to a discretionary fund, donations to which may be used in part or in whole at their discretion for the benefit either of the hospital or of the medical school. While careful that all money contributed for hospital purposes shall be expended only in the relief of the sick poor, the Governors, recognising the importance of the medical school, have opened this fund to be allocated between the hospital and school in proportion to their respective needs.

PREVENTION OF EPIDEMIC DIARRHŒA.—A circular (No. 217, H.M. Stationery Office, price 1*d.*) has been addressed by the Ministry of Health to local authorities carrying out maternity and child-welfare schemes on the subject of the prevention of epidemic diarrhœa. Though the mortality from this disease of infancy has steadily decreased, a hot spell such as that through which we are at present passing may cause a sudden and serious rise. In view of the fact that epidemic diarrhœa is essentially a disease of urban communities, and is more liable to affect areas unprovided with satisfactory water closets, it is desirable to make sure that accumulations of dust or refuse, and the contents of privies, pail, or tub closets are removed frequently, and that foodstuffs are screened from flies. In the event of a threatened epidemic of diarrhœa local authorities are advised to suspend routine home-visiting and welfare work, and to employ the total available staff in an attempt to prevent the spread of infection and in the nursing treatment of sick infants. Mothers should be instructed to continue breast feeding during the hot months, and to apply early for medical advice. Voluntary notification of the disease to health visitors by the mothers, and to the local authority by medical practitioners, will ensure arrangements for immediate assistance in nursing. Domiciliary nursing should be provided where possible, in order that the instructions of the medical practitioner in charge of the case can be carried out, and disinfectant solutions provided for soiled clothing. Hospital accommodation should be made available for children who are seriously ill in special wards.

THE LATE DR. REYNOLDS RAY, OF DULWICH.—Dr. Ray, who practised for many years in Dulwich and afterwards in London, died at the age of 79 on July 8th. He was in busy practice to within six months of his death, retaining a vigour of mind and body unusual at his age. He was educated at Guy's Hospital, qualifying M.R.C.S. Eng. in 1863 and subsequently becoming house surgeon at Guy's. He left hospital to help in the practice of his father, whose health had begun to fail; otherwise he might have obtained some position on the staff of the hospital, since he was one of the best students of his time. He was greatly respected, trusted, and beloved by many, and held for a long time a leading position in Dulwich. Dr. Ray was a sportsman, an expert fisherman, and a good shot and whip. As a breeder of bloodhounds he took prizes with dogs which became famous, and for 50 years he was a member of the Kennel Club. He became a special constable during the war and led his section at the parade before the King. As just 60 years previously he marched in review of the newly raised Volunteers, he had a record few could surpass. While taking night duty three times a week with charge of the ambulance, Dr. Ray attended daily at the Horton Military Hospital at Epsom. Here he won the esteem and affection of patients and staff alike, and here he worked throughout the epidemic of influenza. A sound practitioner, a warm-hearted, sincere friend, a man of high ideals, and a thorough sportsman, he will be missed by a large circle of friends.

EAST SUSSEX HOSPITAL.—At the eighty-first annual meeting of the hospital on June 29th it was reported that but for extraordinary income the deficit on the year's working would have been £1096. Since November last patients had been asked to contribute a minimum of one guinea per week towards their maintenance, and while this had somewhat alleviated the financial distress the Committee felt that they must continue to look to subscribers and donors for their support in order to make way against the ever increasing difficulties. Reference was made to the report of Lord Cave's Committee. Lord Eustace Percy said in the first place they had to face this fact—that the Government, and, he thought, the majority of public opinion throughout the country, was very strongly in favour of retaining the voluntary principle; and in the second place

Correspondence.

"Audi alteram partem."

PSYCHOTHERAPY.

To the Editor of THE LANCET.

SIR,—I shall be obliged if you will insert the following short comments on Dr. S. Herbert's letter in THE LANCET of July 16th. (1) Dr. Herbert writes in reference to my letter of the previous week: "I did not confuse psychotherapy with psycho-analysis." But I did not make this charge against him, and I specially pointed out that he used the word "psychotherapist" with its proper meaning. What I emphasised was the prevalent trend towards the confusion of "psychotherapy" with "psycho-analysis," which is undeniable. (2) Dr. Herbert writes of my "bias" against psycho-analysis. By this I suppose he means my opposition to the greater part of the Freudian teaching, and, if so, I fully accept the imputation of "bias." No one can reason on any matter without some bias towards one or other method of approaching it. (3) Dr. Herbert, in referring to my use of the words "false psychology" implies that I intended to brand all Freudian views and writings with falseness. This was not my intention. When I wrote that "the importance of the sex-factor in the genesis of mental disturbances was emphasised long before this doctrine was exaggerated, transformed, and linked up with what most scientific thinkers deem to be a false psychology," I meant, of course, by "false psychology" the basic assumption of Freudians, the hypothesis of the "Unconscious Mind," and thought that my meaning was clear.

I am, Sir, yours faithfully,

London, July 16th, 1921. H. BRYAN DONKIN.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of THE LANCET.

SIR,—Dr. I. Harris, in his letter in your issue of July 9th, has not accurately defined the issue of this discussion. It is not whether an increased flow per time unit can be obtained through the arterial system in the presence of lowered blood pressure. This I do not deny. In fact, I have agreed that this is possible under such circumstances, *provided* there is vaso-dilatation. Dr. Harris, on the other hand, declares the increased flow possible in the presence of lowered pressure and in the absence of vaso-dilatation. This I deny. If there is no vaso-dilatation, then the arterial passages and exits remain as before. But to urge through undilated passages a greater blood volume per time unit demands the exercise of a greater driving force to accomplish the assuredly greater work, and *there is nothing miraculous about digitalis which* suspends the operation of this physical law. The force of cardiac systole must, therefore, be increased, and concurrently a correspondingly greater pressure (the other factor determining flow) be exerted by the arterial walls on the circulating blood. The blood is driven in greater volume and with greater force into the arteries and exerts upon them a greater pressure. Effective resistance is offered to this by the (according to Dr. Harris) undilating vessels, and the intra-arterial pressure rises. In this manner is obtained the greater force required to accomplish the greater work, and in consequence of it the velocity of the blood stream rises and a greater delivery per time unit is effected. It is obvious that this is the mechanics of our problem. Dr. Harris may sneer at what he calls "empty phrases such as physical laws," but I assure him that physical laws are laws, and that a series of disconnected statements divorced from reality and loosely held together by sophistic, formal reasoning does not suspend their operation.

I regret that Dr. Harris does not see fit to support the cardinal assumption of his paper—viz., that increased pulse pressure connotes increased cardiac output, and vice versa. The fallacy in this assumption vitiates all his conclusions. I did not accept it in my first letter, but "assumed it with Dr. Harris" merely in order to erect upon it an "*argumentum ad hominem*." In conclusion, I regret that Dr. Harris should misquote me and father me with a statement which I would not make. I did not say it is impossible to get an increased flow per time unit through the veins without an increase of pressure in them. I do know something about the function of negative pressure in venous flow. What I did say was, "If the pressure in the veins is not increased, these will be unable to pass a greater amount of blood per time unit into the heart *at the increased pressure* necessary to cause the rise of intra-cardiac pressure depicted by Dr. Harris." This is quite a different statement, and its truth is so obvious that one need not labour the point. As far as I am concerned this correspondence ceases. I am, Sir, yours faithfully,

Eltham, July 9th, 1921. W. J. GRANT.

THE VALUE OF SANATORIUM TREATMENT.

To the Editor of the LANCET.

SIR,—My personal experience tallies closely with that of Dr. F. G. Caley (THE LANCET, June 18th), as to the disappointing results of sanatorium treatment, both in its individual aspect and from the economic and public health standpoints. Sanatorium medical officers are frequently unversed in knowledge of other tuberculosis therapy, and denied the opportunity of seeing the after-results of cases which have left their immediate care. The percentage of post-sanatorium relapses is comparatively high, often within a short time, making the expenditure, both public and private, out of all proportion to the private good. In sanatorium treatment *per se* there is nothing specific—i.e., capable of destroying the tubercle bacillus or the allied organisms which foster its activities.

Sanatoriums are undoubtedly of considerable value from the educational point of view, but residence therein for a term of from six weeks to three months is ineffective in doing more than in most cases temporarily to raise auto-resistance. But what of the patient with a bad family history of tuberculosis, or in whom resisting power is dangerously low, either naturally or as the result of a virulent infection or other intercurrent factors? Such cases are many and provide that failure to react which ends in a fatal issue at no remote period.

No absolute specific has yet been discovered, but the method that, during the past nine years, has given me the best all-round results in all cases except the advanced, is found in intensive nascent iodine therapy. This does not contra-indicate sanatorium treatment as well, if desired, but can readily be used apart from the latter. The treatment can be administered either orally or by ionisation, the latter procedure being by far the more rapid.[1] Iodine, evolved from iodide by a powerful reducing agent given in successive doses, or by ionisation, in my experience is of more value than administration of "intensive" drop doses of the French tincture, following the practice of Bourdreau. Although the latter procedure is simpler, the liability to gastric disturbance is greater, and a commensurate effect upon tuberculous foci is not so readily obtained. The waxy lipoid coating of the tubercle bacillus renders it at the same time hard to stain and difficult to destroy in situ, and iodine is the only effective germicide that can be introduced into the body in sufficient non-toxic concentration to dissolve this coating, to cause cell proliferation and promote catalysis, processes similar to what can be readily

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Clinical Thermometers Bill.

THE text has been issued of the Clinical Thermometers Bill which was recently introduced by Mr. BALDWIN, President of the Board of Trade, into the House of Commons. The administration of an Order made by the Ministry of Munitions requiring that clinical thermometers should be tested and marked before sale was transferred to the Board of Trade in June, 1919, and the Order was discontinued as from April 1st, 1921, by the Ministry of Munitions (Cessation) Order, 1921. The present Bill proposes to place the requirement on a permanent statutory basis. The testing of clinical thermometers will be undertaken by the National Physical Laboratory, which performed all the testing required during the war. As the fees charged by the National Physical Laboratory for testing clinical thermometers will cover the cost, the Bill will not involve any charge upon public funds. The penalty for an offence under the Act is a fine not exceeding £10.

HOUSE OF LORDS.

TUESDAY, JULY 19TH.

Coroners (Remuneration) Bill.

The Coroners (Remuneration) Bill was read a second time.

National Health Insurance Bill.

The National Health Insurance Bill was read a third time and passed.

HOUSE OF COMMONS.

TUESDAY, JULY 12TH.

Deaths from Vaccination.

Mr. WATERSON asked the Minister of Health whether the letters addressed to medical men who had certified deaths as due to vaccination, and the visits of medical officers of the Ministry to make personal inquiries into the circumstances, had resulted in an alteration of the death certificate; and, if so, in how many cases had this occurred. —Sir A. MOND replied: The answer to the first part of the question is in the negative, and the second part does not therefore arise.

Homes for Shell-Shock Cases.

Brigadier-General SURTEES asked the Minister of Health whether there was now any prospect of the establishment of homes for those ex-Service men who were mentally afflicted owing to shell-shock, and who were now confined in company with certified lunatics.—Sir A. MOND replied: I am informed that the Board of Control is not aware of any ex-Service men in asylums or hospitals for the insane other than those who have been certified as insane. Amongst them there are cases in which insanity has supervened upon shell-shock. There are several neurological hospitals under the control of the Ministry of Pensions where ex-Service patients whose mental symptoms do not amount to confirmed insanity are being treated.

WEDNESDAY, JULY 13TH.

Treatment of Tuberculosis.

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Health how much had been spent under the Insurance Act since July, 1912, in the treatment of tuberculosis.—Sir A. MOND replied: I assume that my hon. friend refers only to expenditure on the provision of sanatorium benefit for insured persons under the Insurance Acts. The amount spent in England and Wales upon the provision of sanatorium benefit for insured persons under the Insurance Acts from July, 1912, to April 30th, 1921, the date on which the benefit terminated, was approximately £6,380,000.

Government of Greater London.

Mr. JESSON asked the Minister of Health (1) when it was proposed to appoint the committee that was to inquire into the question of Greater London government; and, if the inquiry was not held this year, if it was intended to act upon its findings during the life of the present Parliament. (2) If, having regard to the importance of the fact that the ratepayers of districts that had received the honour of incorporation took a greater interest in public affairs, he proposed to withdraw his objections to the incorporation of Walthamstow in the event of the inquiry into the government of Greater London not being held this year.—Sir A. MOND replied: As has already been stated in reply to previous questions the Government are considering the question of instituting an inquiry into the local government of London and Greater London. Until a decision has been reached I am unable to add anything to the answer I gave my hon. friend on July 6th with regard to the incorporation of Walthamstow.

Poor-law Children in Sick Wards.

Mr. ANEURIN WILLIAMS asked the Minister of Health the total number of in-door Poor-law children, the number of children over and under 3 years of age who were in sick wards and other wards, respectively, of workhouses, and the number of children in receipt of out-door relief on Jan. 1st, 1921.—Sir A. MOND replied: The number of children in receipt of institutional relief on Jan. 1st, 1921, was 60,672. Of these there were: In sick wards of workhouses, over 3 years of age, 2365; under 3 years of age, 2505. In other wards of workhouses, over 3 years of age, 2553; under 3 years of age, 3365. The number of children in receipt of out-door relief (including children boarded out) on the same date was 174,097.

Dismissal of Nurses at Steyning Infirmary.

Mr. THOMAS GRIFFITHS asked the Minister of Health whether it had been brought to his notice that two nurses in the Poor-law services at Steyning Infirmary, Brighton, having passed their examinations, had been dismissed at a few hours' notice, and refused their certificates; whether he was aware that a member of the committee appointed to inquire into the matter stated that he had found the charges made against them to be without foundation; and whether, as the shortage of nurses was so great that it was a matter of public importance that suitable women should not be discouraged from entering the nursing profession, he would hold an inquiry into the matter.—Sir A. MOND replied: I am informed by the Board of Guardians that they appointed a special committee to inquire into this case, and that the committee came to the conclusion that the charges made against the nurses had been proved, and that they had been guilty of gross unkindness to a patient, and also of insubordination. I am also informed that the guardians have decided to furnish the nurses with an extract from the minutes of the Board. stating that they had passed the examination. In these circumstances I do not think that any useful purpose would be served by my directing a further inquiry into the matter.

Merchant Seamen and Venereal Disease.

Mr. MILLS asked the Minister of Health if he was aware that British seafarers still suffered under disabilities unshared by their fellow-countrymen or by foreign seamen in being penalised if they sought treatment for venereal disease, and that the British representatives at the meeting of the health section of the League of Nations were advocating international facilities for the free treatment of seafarers; and if the Government would consider the desirability of amending the Merchant Shipping Act, 1906, Section 34, subsection (1), as desired by all interests concerned.—Sir A. MOND: As regards the first part of the question I would refer the hon. Member to the reply to the same question on April 26th last. As regards the second part I understand that my right hon. friend the President of the Board of Trade proposes to include a clause for this purpose in the next general Merchant Shipping Bill.

Children in Village Communities, &c.

Mr. HASLAM asked the Minister of Health whether he would state the number of children maintained under each of the three following systems on Jan. 1st, 1921: Poor-law schools, village communities and grouped cottage homes. and scattered homes —Sir A. MOND replied: The number of children in the following classes of Poor-law establishments for children on Jan. 1st, 1921, were: schools, 7429; grouped cottage homes, 11,793; scattered homes, 7916; other separate homes and insitutions for children (including a training ship), 4224.

THURSDAY, JULY 14TH.

Medical Services in the Colonies.

The House went into Committee of Supply on a vote of £529,104 for the salaries and expenses of the Department of the Secretary of State for the Colonies, Mr. JAMES HOPE in the chair.

Sir D. MACLEAN moved that sub-head A (salaries, wages, and allowances, £145,143) be reduced by £500.

Mr. E. WOOD (Under-Secretary for the Colonies) said they ought never to forget that whether the human race was at peace or at war, the warfare that the lower creation, in its instinctive task of carrying and disseminating disease, waged upon it was perpetual and unrelenting, and that in that warfare there was no neutrality. To anybody who would investigate them the discoveries that had been made and the successful efforts that had been put forth in that field during the last 20 years formed a real romance, but quite frankly he said that as far as he had been able to form a

UNIVERSITY OF LIVERPOOL: FACULTY OF MEDICINE.—The following candidates have been successful in examinations recently held:—

DEGREE OF M.D.

N. B. Capon, R. W. Gemmell, W. E. Huff-Hewitt, W. A. Jackson, and C. V. Pearson.

DEGREE OF CH.M.

J. St. G. Wilson.

DEGREES OF M.B. AND CH.B. (HONOURS).

Class I.—*†G. W. Phillips.

Class II.—G. P. F. Allen, ‡A. V. Campbell, *S. B. Herd, *Isabel E. Imison, *M. Newman, and *S. V. Unsworth.

FINAL EXAMINATION FOR M.B. AND CH.B. DEGREES.

Part I.—B. Abelman, G. C. Bhatia, R. H. Blair, R. L. Blair, N. B. Cooke, W. H. A. Dodd, J. O. Edwards, E. H. Glynn, C. B. Lewis, I. Lloyd, J. R. Parry, G. F. G. Prideaux, and J. K. Reid.

Part II.—‖Ethel Ashton, E. W. Ashworth, Eudora V. Beatty, R. H. Blair, R. L. Blair, D. Brown, Hilda Cantrell, A. Cathcart, G. Clark, Marie B. Clarke, H. M. Cohen, §‖H. Cohen, §‖M. J. Cohen, N. B. Part III.—F. H. Alexander, G. C. Bhatia, Doris Brown, W. E. A. Burton, Doris M. Cassady, W. M. Frazer, G. L. Gatoly, Susan H. Gilchrist, J. Goldberg, Isobel K. Johnstone, R. J. Jones, A. Livingston, H. R. Madan, J. B. Oldham, T. R. Roberton, S. S. Skri-Kent, C. Voigt, and T. A. Williams.

DIPLOMA IN PUBLIC HEALTH.

W. H. Brown, M.B., Ch.B., Gladys E. Chambers, M.B., Ch.B., B.A.O., J. H. Crane, M.D., A. Hamid, M.B., B.S., Dorothea E. Hewitt, M.B., Ch.B., Mary A. McHugh, M.R.C.S., L.R.C.P., R. Nixon, M.B., Ch.B., C. M. Ram, M.B., H. Rawsthorne, M.R.C.S., L.R.C.P., and Dorothy M. Unsworth, M.B., Ch.B.

* Distinction in Obstetrics.
† Distinction in Medicine.
‡ Distinction in Surgery.
§ Distinction in Forensic Medicine and Toxicology.
‖ Distinction in Public Health.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE SCHOOL OF PHYSIC.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—*John C. Earl, *James O'N. McKenna, *Paul J. Grobler, *George F. T. Saunders, *William F. Whaley, *Robert H. Micks, *Robert T. Jackson and *Matthys P. Louw (equal), Dermod H. F. Milmo, Max Wulfsohn, Douwe M. Vellema, Reginald Hegy and John Ditton Wicht (equal), Mauritius M. Viljoen, Michael Gallivan, Louis J. Coetzee and Lazarus Heyman (equal), Alice M. A. Downing, John H. J. Stuart, David L. H. Moore, Jan H. Rauch, Rupert L. Hill and Frederick W. G. Smith (equal), William S. Dixon, Cecil de Lisle Shortt, Cecil G. S. Van Heyningen and Barend Vivier (equal) and Alexander Bernstein.

Pathology and Bacteriology.—Samuel Wilfrid Russell and Herbert Hall.

Materia Medica and Therapeutics.—Robert Nelson Perrott.

Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene.—Joseph Harte.

Part II., Medicine.—*Margaretta T. Stevenson, Alida C. Burt and Alice E. Lawlor and Albert E. Phillips (equal), Richard V. Dowse, Constance McIlrath, Albert V. J. Russell, James Devane, John D. Thompson, Doris Holland, Emily E. G. Baillie, John C. Brennan, Michael R. Coolican, Robert R. Baker, William H. Smith, Gideon C. Malherbe, and John M. Semple.

Midwifery.—*Cyril J. U. Murphy, *Izak G. Sacks, *Cornelis D. Dijkman and *Albert V. J. Russell (equal), *Doris Holland, Gilbert M. Irvine, Beryl F. E. Cockle and Theunis de Bruijn and Daniel Hugo (equal), Emily E. G. Baillie, Charles Theodore de Mornet Villet, Cecil S. Wilson, Francis Malone-Barrett, Cecil de Lisle Shortt, Hector C. C. Deane, Francis M. Hilliard, Thomas W. Panter, Max Elion and George C. B. Robinson (equal), Margery Bouchier-Hayes, and William S. Dickson.

Surgery.—*Eric Sealy Horgan, Lionel Wigoder, Edith F. Willock, Eric R. Murray and Albert V. J. Russell (equal), Olive V. Fair, Nannette Norris, Albert S. Bradlaw, Alice E. Lawlor, Patrick M. J. Bobbett and Anthony D. Ward (equal), and John M. Semple, Michael R. Coolican, and James C. Davis.

* Passed on high marks.

DIPLOMA IN PUBLIC HEALTH.

Part I., Chemistry, Bacteriology and Pathology; Physics and Meteorology.—Edward D'A. McCrea and Richard P. Pollard (equal). Alan G. Wright, and William B. J. Pemberton.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following have been elected to Burney Yeo Scholarships: H. A. Robertson, M.A., Balliol College, Oxford; R. Cove-Smith, B.A., Gonville and Caius College, Cambridge; L. C. Whitworth, B.A., Downing College, Cambridge. On the results of the June examination the following awards have been made: Senior Scholarship (£10), Tanner Prize (£10), Todd Prize (Medal and £4 4s.), and Class Prize in Diseases of Children, R. C. Lightwood; Class Prize in Orthopædic Surgery, J. W. Hirst; Class Prizes: Medicine, H. Moos; Forensic Medicine and Hygiene, M. W. Hubble; Psychological Medicine, E. Murgatroyd.

BELGIAN RED CROSS.—A letter has been addressed by Dr. A. Depage, the President of the Belgian Red Cross Society, to every physician in Belgium announcing the adhesion of the Society to the League of Red Cross Societies, and stating that the peace-time activities of the Red Cross cannot be put on a satisfactory basis until the membership is multiplied tenfold. In view of the important part which physicians must play in the future Red Cross activities a special appeal is made for their support in the formation of local committees. The letter appears in full in *Le Scalpel* for June 4th (p. 463.)

LEAGUE OF RED CROSS SOCIETIES.—The meetings of the Medical Advisory Board, consisting of Sir George Newman (England) in the chair, Prof. Cesare Baduel (Italy), Prof. Léon Bernard (France), Prof. Th. Madsen (Denmark), Dr. Prochaska (Czecho-Slovakia), Dr. Linsly R. Williams (United States), were held at Geneva, and lasted from July 5th to 7th. It was decided to concentrate the efforts of the League upon "public health objectives obtainable through the medium of Red Cross effort . . . coöperating as closely as possible with all official and voluntary agencies having the same purposes in view." Special attention is to be paid to the development of public health nursing, and to the problems of child welfare, tuberculosis, and venereal diseases. The *International Journal of Public Health* has given such good promise of filling a recognised need that it is to be continued substantially along its present lines The Board was so impressed with the success of the international conference on venereal diseases recently organised by the League that they recommend that similar conferences be arranged in child welfare. The continuation of regional conferences on venereal diseases is also recommended.

DIPLOMA IN NURSING AT THE UNIVERSITY OF LEEDS. The reputation of Leeds as a training centre for nurses has been for many years a high one. The General Infirmary affords opportunities for acquiring a knowledge of all branches of nursing; and especially during the last few years there has been a steadily growing desire on the part of the board to supplement the practical training by the teaching of principles. The nurses are appointed by the board on the recommendation of the lady superintendent; they may enter at the age of 20, and in some instances they have been admitted at the age of 19. For their first three months they work as "pupil nurses," and of this time six to eight weeks is spent in the preliminary training school. If at the end of this time they are found satisfactory and have passed a medical examination as to their physical fitness they are admitted to training as probationers and continue in that capacity for 12 months, the time spent as pupil nurse counting as a part of that period. If at the end of the 12 months they are still considered efficient they sign on for a further period of three years. It will, therefore, be seen that the period of training extends over four years and no nurse now gets a certificate on a shorter course of training. The institution of the preliminary training school has been a great success; under the careful and personal supervision of the special sister tutor the pupils are introduced to the alphabet of the subject, those who have no aptitude for the work are sifted out, and experience has shown that a nurse becomes of more use to the infirmary in a shorter period than during the old régime when the probationer found herself in the wards from the beginning. During the years of her training the nurse attends a carefully graduated course of instruction. Lectures are given by the members of the professorial staff of the University, many of whom are, of course, on the infirmary staff, and practical demonstrations are given in the wards and in the post-mortem room. Care is taken to secure the widest possible variety of training, but at the same time those who show special predilections for medical or surgical work are encouraged to specialise towards the end of their training. A large number of nurses who have passed through the training of the General Infirmary now occupy positions of responsibility and of trust in the nursing world, and special facilities are given to selected nurses to acquire a knowledge of housekeeping and of hospital administration. Some time ago the University of Leeds was approached with a view instructions to boards to notify the local committee in such circumstances are not obeyed. I am, however, having inquiry made into the position in the Manchester area, and will communicate the result to my hon. and gallant friend.

Men Disabled in Former Wars.

Sir **ROBERT NEWMAN** asked the Minister of Pensions whether ex-Service men, who had been totally disabled through service in His Majesty's forces prior to 1914, were receiving the same pension as men totally disabled through services under the Crown since that date; whether the widows of ex-Service men, who lost their lives through service in the forces previous to the recent war, were receiving the same pension as widows whose husbands lost their lives since 1914; and, if not, whether His Majesty's Government would consider the advisability of taking steps to place the older ex-Service men and their dependents on the same footing as the younger ex-Service men and their dependents.—Mr. **MACPHERSON** replied: Men disabled through service in former wars are now entitled to pension at the increased rates applicable to men disabled in the great war, and the pensions previously in payment to the widows of men who died in former wars have been similarly increased. If my hon. friend is referring to disability or death incurred on military service in peace-time, he should address his question to my hon. friend, the Secretary of State for War.

Production of Calf Lymph.

Mr. **MILLS** asked the Minister of Health how the carcasses of the calves used for the production of vaccine lymph at the Government lymph establishment were disposed of after the lymph had been taken from them, and the animals had been slaughtered.—Sir A. **MOND** replied: The calves used for the production of lymph at the Government lymph establishment are hired and after slaughter the carcasses are examined by the veterinary surgeon of the establishment. The carcasses sold for food are subject to further examination by officers of the local sanitary authorities. I am advised that there is no evidence whatever that the carcasses of vaccinated calves are unfit for food.

Government Housing Policy.

Replying to questions by Mr. **HOGGE**, Major **PRESCOTT**, and Mr. **TREVELYAN THOMSON**, Sir A. **MOND** (Minister of Health) said that the number of houses built, building, and contained in approved tenders under the housing scheme for local authorities and public utility societies was now about 176,000. Under the scheme of subsidy to private builders the number of houses built or to be built was estimated at about 23,000. The annual cost to the State under the local authorities and public utility societies schemes was about £10,000,000 per annum, and the amount required for payment of subsidies to private builders was about £5,000,000. The Government had decided that for the time being, at any rate, the number of houses to be constructed by local authorities and public utility societies, with Government assistance under the present scheme, would be limited to 176,000. It would appear that on a final examination of the present approved tenders some adjustments would be possible to meet cases of hardship without exceeding this total. All expenditure in connexion with the housing schemes which had already been incurred by local authorities, with the approval of the Ministry of Health, would rank for financial assistance under the present scheme, which limited the liability of local authorities to the produce of a penny rate, and where work undertaken by local authorities, with the approval of the Ministry of Health, could not, for reasons outside the control of the authorities, be completed by July, 1922, the time for completion would be extended by the Ministry as might be necessary. As regarded the scheme of subsidy, payment in full would be made for houses completed within the four months after the expiration of the present Act—i.e., by April 23rd last, and additional houses would only be subsidised if begun before July 1st under a certificate or the promise by a local authority of a certificate. In cases where commitments had been entered into, although construction had not actually been begun, in anticipation of the continuance of the subsidy, he would, in the exercise of his discretion, pay such subsidy in such cases if work was started within six weeks of the present date. The Government recognised the urgent necessity of making what improvements were possible under present financial circumstances in slum areas, and they were prepared to provide an annual contribution not exceeding £200,000 towards the deficiency on local authorities' accounts for the improvement of slum areas. This annual contribution would continue for the whole term of such loans as might have to be raised by local authorities to defray the necessary expenditure. It was the intention of the Government to keep the housing problem closely under review. They fully recognised the importance of that problem from the point of view of the health and social conditions of the people, but it was impossible to incur greater commitments than our finances would allow.

Dr. **ADDISON** (Minister without portfolio, and formerly Minister of Health, who was responsible for the Government's housing policy until recently) rose and intimated his resignation from the Government in consequence of what he described as "the precipitate abandonment of an effort which is so essential to national restoration." He regarded it as a betrayal of the Government's solemn pledges to the people and of their obligations to the local authorities and to many individual citizens, as well as being calculated to weaken the confidence of the people in the reliability of constituted authority.

Mr. **CHAMBERLAIN** (Lord Privy Seal), in the absence of the Prime Minister, expressed the gratitude of his late colleagues in the Cabinet to Dr. Addison for the help which he gave them in a difficult work and in a difficult time, and their regret that he should have felt it his duty to sever his connexion with them.

FRIDAY, JULY 15TH.

Criminal Law Amendment Bill.

Major **FARQUHARSON**, in moving the second reading of the Criminal Law Amendment Bill (which has been passed by the House of Lords), said that it was a step in the normal evolution of the law on the subject. In the Bill the limit of childhood was placed at 16, and it was right that the fullest protection of the law should be given to the period of childhood whether in regard to sexual offences or offences under the various Children's Acts. Apart from the question of sexual relationship and as an evolutionary step in legislation, speaking as a doctor, he ventured to submit certain views which he held with regard to the biological and scientific aspect of this question. In the whole range of nature there was in the human mammal an abnormally long period of dependence of the child upon the parent for parental care, and it seemed to him that it was nature's penalty or nature's price for the qualities of latent and potential excellence with which the human race was endowed and which our higher civilisation had cultivated. There was no period during the time of childhood so urgently calling for protection as the period between 13 and 16 years of age. It was that time when strangely enough the sex instinct was appearing in the blossom. That instinct gave an unconscious stimulus to the ego, a desire for independence, a seeking after individuality, a certain degree of rebellion against parental discipline. At that period there was a certain hiatus between parental care and the needs of the child, and it was time when the State should step in to exert every form of protection it could for the child during those tender years. The public health aspect of the Bill appealed very strongly to him. The very conditions in the last half century suggested to him that an enormous amount of physical disability which they found prevalent during the war was directly traceable to the conditions of life during that past half century. He was perfectly certain that an enormous amount of the venereal disease which prevailed—he would go so far as to say 80 per cent.—was transmitted by children and very young persons. From the point of view of its relations to the past, the biological point of view and in relation to public health, he seriously commended this view to the House. No measure would be more fraught with good for the prevention of not only prostitution, but that the whole thing would tend to bring home to the very young the nature of this matter and would save them from embarking on a career of vice. He spoke thus from his medical experience. This was a Bill for the protection of our race and a stepping-stone to a greater and higher physical efficiency than we had secured in the past.

Mr. **WIGNALL** seconded.

Major **CHRISTOPHER LOWTHER**, in moving the rejection of the measure, said all of them were equally keen to secure greater morality and better health among the population, and to see that young persons should not have gross offences committed against them. But he did not believe they could cure immorality by legislation; the proper way to effect that was by education and proper protection of the children by parents and guardians, rather than by legislation which was directed to take away from an accused person practically his only defence. He pointed out that it had been shown in a large number of cases in the Assize Courts that young women had not only consented but had incited men to commit offences. The age of 16 was a very arbitrary one. These questions were matters of temperament and nationality. There were in this country a large number of young Indians, Spaniards, and Jewesses who were plying the trade of prostitutes on the streets of London. They had every appearance of being 18 or 19 years of age. He was informed that if this Bill was passed there would be great difficulty in getting a jury to convict in cases of this kind. It was really an appalling thing that in this E they had to face the fact that any temporary subsidy which might be given towards the maintenance of voluntary hospitals, apart from any interference with them was practically certain to be less even than the urgent needs of these hospitals. Lord Cave's Committee had recommended a subsidy of one million pounds, but it was stated that the Government proposed to give only half a million, and that, Lord Eustace Percy thought, was the limit of what the voluntary hospitals could expect to receive. The position of the East Sussex, as of all hospitals at the present time, was a serious one. A very large increase of voluntary support was needed, especially in view of the approaching removal of the hospital. The in-patients during the year reached the record figure of 1075. The out-patients numbered 4285, a slight decline, but the number of out-patients' attendances, 51,525, showed a considerable increase. This increase was largely accounted for by the new massage and electricity department which had been installed, in addition to which the hospital was now equipped with radiant heat and ultra-violet rays. The announcement was made at the meeting that the erection of the new hospital had already been commenced.

Mr. E. Gerald Stanley, M.S.Lond., F.R.C.S.Eng., has received the Doctorate of the Faculty of Medicine of Paris with honours.

DONATIONS AND BEQUESTS.—The Chelsea Hospital for Women has received £105 from Mr. and Mrs. Sannyer Atkin towards its nurses' home.—Under the will of the late Mr. John Boultbee Brooks, of Finstall Park, Worcester, the testator gave £1000 to the Children's Hospital, Birmingham; £500 each to the General Hospital, Birmingham; Queen's Hospital, Birmingham; the Cottage Hospital, Hinckley, and the Cottage Hospital, Bromsgrove.

BRISTOL MEDICAL COMMITTEE.—In July, 1919, the practitioners of Bristol, convened by the local division of the British Medical Association in concert with other medico-political organisations, resolved to elect a "committee, to be called the Bristol Medical Committee, which shall be representative of all sections and interests of the profession"; and authorised the committee thus formed to consider questions relating to medical practice arising within the city, and, with certain reservations, to take necessary action with regard to them. The committee elected in 1919 carries on till early in 1921, when, under its own regulations, a new committee was elected. This new committee was charged with the task of considering the Dawson Interim Report and the applicability of its proposals to Bristol. By way of preparing the ground for so considerable a task the committee decided to take stock of the various forms of medical service already at work in the city. To this end medical officers in charge of these services have been invited to address the committee, and also to furnish reports on the work of their respective departments. This invitation has been accepted very willingly, and several valuable addresses have already been delivered. It is hoped that at the end of the session a comprehensive report may be prepared so that all the possibilities of a coördinated plan of medical service within the city may be fully examined.

THE LATE DR. EDGCUMBE BURROWS.—The death of Dr. W. Edgcumbe Burrows, district surgeon of Bothaville, South Africa, and acting district surgeon of Kroonstad and district, took place in April at Kroonstad. Dr. Burrows was the eldest son of the Rev. J. Burrows, of Walsall, and was born at Dudley, Worcestershire, in 1882, receiving his education at Bath and Durham University. He took the degree of B.Sc. in 1902, and entered the Middlesex Hospital, obtaining his M.B., B.S., in 1906. He married Miss E. Clare Williams, the only daughter of the late Captain Williams, of Clifton, in the same year, and for the following eight years practised at Manor Park, London, taking the degree of M.D. London in 1913. He joined the Royal Army Medical Corps in March, 1915, and served in France until 1917, being mentioned in despatches in June, 1916, for conspicuous bravery under heavy fire. In 1917 Dr. Burrows was sent to German East Africa, and was slightly wounded and again mentioned in despatches for bravery, attention, and care of wounded under very heavy fire. Later he had charge for a time of the 19th Stationary Hospital in Portuguese East Africa. After demobilisation he joined the South African Medical Corps, being stationed at Wynberg and afterwards at Pretoria; he resigned in January, 1920, and proceeded to Bothaville to act for Dr. W. A. Carden (during the latter's absence in Europe) as district surgeon for the Bothaville area. Here he was joined by Mrs. Edgcumbe Burrows and son, who arrived from England during 1920. Dr. Burrows won the respect and affection of all sections of the community by his unselfish devotion to duty, and his untimely death is regretted in Bothaville and throughout the district.

The Services.

SHIPS' LAUNDRIES.

THE Admiralty is steadily increasing the comfort of the sailors in their ships. Laundry machinery is now to be fitted in the *Queen Elizabeth* and other large ships.

HEALTH OF THE FRENCH NAVY IN THE WAR.

The following account of the health of the French Mediterranean Fleet during the war is taken from a review in *Arch. de Méd. Militaire*, of an article by a naval medical officer. The average complement was 33,788—the sick list 1022, the deaths 5·17, and the invalidings 70, in every 1000 men. Anæmia, always prevalent amongst the engine-room staff, was more frequent during this period, as the ships were so constantly under steam. There were 12,115 cases of influenza in 1918 with 196 deaths. Antityphoid vaccination had an excellent effect, more conspicuous in the second half of the war. Prophylactic quinine diminished malaria. Tuberculosis attacked 4 per 1000, and many cases called anæmia may well have been early cases of tuberculosis. Venereal diseases were fewer than in peace, and were reduced by regulating prostitution or by compulsory prophylaxis. Arseniuretted hydrogen, given off from the accumulators of submarines, caused trouble in 1916 particularly, 26 cases in one of these craft and 27 in another in that year. Many men were invalided home because they were simply worn out. The large cruisers are healthy; the large battleships have too little light and air, and they are overcrowded. Steel decks are unsatisfactory, being often too cold or too hot; they must be sheathed in non-inflammable wood, as in England and Germany. Larger steam radiators and heavier clothing are needed in cold climates. Douche baths have been fitted in some ships; the sailors generally wash still in the bucket, long ago condemned. Disinfectors are not numerous enough; washing machines are asked for. Refrigerating chambers have made it unnecessary to carry live animals to sea, and this should be forbidden, as it causes nuisance.

ARMY MEDICAL SERVICE.

TERRITORIAL FORCE.

Capt. (Bt. Maj.) C. H. S. Frankau resigns his commn. and is granted the rank of Col.

ROYAL ARMY MEDICAL CORPS.

Capt. D. T. M. Large relinquishes the temp. rank of Maj.

Capt. H. A. Crouch is placed on the h.p. list.

Capts. W. P. Mulligan, H. Bedingfield, and W. McM. Chesney retire, receiving a gratuity.

Capt. E. J. Mannix is secd. for service under the Foreign Office.

Temp. Capt. G. W. Will to be Capt.

Temp. Capts. J. J. Clarke and D. R. Alexander relinquish their commns. and retain the rank of Capt.

ARMY DENTAL CORPS.

The undermentioned to be Capts.: Lt. (temp. Capt.) W. A. Rankin.

Flight Lts. from R.A.F. Dental Branch: G. T. Charles and D. H. W. Williamson.

The undermentioned to be Lts. with the temp. rank of Capt. but without the pay or allowances of that rank: Temp. Capt. P. E. Brown, Dental Surg. from Spec. List, and Flight Lt. A. Williams, from R.A.F. Dental Branch.

SPECIAL RESERVE OF OFFICERS.

Capt G. G. Allan relinquishes his commn. on account of ill-health caused by Mil. Service, and retains the rank of Capt.

The undermentioned Capts. relinquish their commns., and retain the rank of Capt.: S. A. Withers and A. B. Grant.

TERRITORIAL FORCE.

Lt.-Col. A. D. Moffat, having attained the age-limit, is retired, and retains the rank of Lt.-Col.

Capt. C. H. Welch to be Maj.

Capts. W Leslie and K. B. Dickson (late R.A.M.C.) to be Capts.

Capt. J. J. Scanlan, having attained the age-limit, is retired, and retains the rank of Capt.

Capt. C. H. Allen resigns his commn. and retains the rank of Capt.

5th S. Genl. Hos.—Capt. T. Holmes resigns his commn. and retains the rank of Capt.

TERRITORIAL FORCE RESERVE.

Maj. W. A. Wetwan, having attained the age-limit, is retired, and is granted the rank of Lt.-Col.

DEFENCE FORCE.

S. Midland San. Sect. (D.F.).—To be temp. Capt.: W. H. S. Dunn.

3rd (S. Midland) Fd. Amb. (D.F.).—To be temp. Capt.: B. Astley-Weston.

1st (E. Lancs.) Fd. Amb. (D.F.).—Temp. Maj. R. MacKinnon (Capt., R.A.M.C. (Spec. Res.)) relinquishes his temp. rank.

Notes, Short Comments, and Answers to Correspondents.

THE LAW OF THE HEART.[1]

By Prof. E. H. Starling, C.M.G., M.D., B.S. Lond., F.R.C.P. Lond.

The discovery by Harvey of the circulation of the blood and of the part played by the heart in carrying on this circulation is one of the few scientific discoveries which have become common knowledge. We have to think of the body as a collection of mechanisms or machines, each one of which is doing some form of work for one common end—i.e., the preservation of the body. For this work the oxidisation of the food taken in at intervals during the day provides the energy; thus each part of the body must be supplied not only with food derived from the alimentary canal, but also with the oxygen taken in with the air we breathe into the lungs. Like any other machine, each body mechanism produces, as a result of this consumption of the food, waste gases and other waste products, which have to be carried to the lungs or to the kidneys and there cleared out of the body. It is for this reason that the existence of the higher animal demands a common fluid, the blood, which can carry food, oxygen, or carbonic acid and which is maintained in continual circulation between all the organs of the body, so that the alimentary canal, for instance, may serve, for the maintenance of all parts and the lungs can supply oxygen to these parts, or collect the carbonic acid which is produced as a result of their activity.

But a uniform mechanical circulation would be of little value to the body, since the activities of all its parts vary within wide limits. Thus during muscular exercise the activity of the muscles may be increased ten-fold or more, and this increase means a corresponding augmentation in their call for oxygen and in the quantity of waste products, especially carbonic acid, that they produce. Since the oxygen is carried by the blood it follows that for the continued functioning of the muscles they must receive a blood-supply which is ten times greater during activity than during rest, if their activity is not to be brought to an end by a species of suffocation. We thus see that in any violent exercise involving the greater number of the muscles of the body, the circulation must be increased in force seven to ten times, and the heart, which is the pump maintaining the circulation, must under these conditions do from seven to ten times as much work as during rest.

The Mechanism of Adaptation.

What is the mechanism of these adaptations? How is it that the heart is able to carry on a circulation which may vary from a passage of 3 litres of blood per minute up to 30 litres of blood per minute (these figures representing the extreme limits between which the output of the heart pump may vary according to the condition of the body). It might be thought that we are dealing here simply with the influence of the central nervous system, which adapts the activity of the muscles of the body to the requirements of the environment, and that the heart being a muscle would be stimulated to contract more strongly at the same time as soon as the latter calls into activity the voluntary muscles of the body. There is no doubt that the heart is under the control of the nervous system, so that its action can be altered, increased, or diminished by the brain in accordance with the needs of economy, but in the heart we find also a wonderful power of adaptation to the varying needs of the organism which is quite independent of the central nervous system.

This can be shown quite easily either in the cold-blooded or warm-blooded animal. The heart of the frog and tortoise can be cut out and will continue beating for hours or even days. It has long been known that the heart of the mammal would beat for some minutes after being cut out of the body, but if we take pains to ensure that the muscles constituting the walls of the heart continue to receive their supply of oxygenated blood, the mammalian heart can be made to beat for 8 to 12 hours after the death of the animal from which it is taken. In order to investigate this properly we want to make such a preparation that we can control at will all the conditions which may effect the action of the heart—viz., the amount of blood flowing into the heart from the big veins, the resistance which the heart has to overcome when it drives the blood out into the arteries, and the temperature at which the heart contracts. We must be able to measure at any time the output of the heart, the arterial pressure it maintains, its changes in volume during contraction, the pressure in all its cavities during each contraction, the amount of blood flowing through the blood-vessels of its walls and its chemical exchanges as measured by the amount of oxygen which it takes up and the amount of carbonic acid which it produces. It is these chemical changes which give the energy for the work of the heart.

The Heart-Lung Preparation.

All these procedures and controls can be carried out in the heart-lung preparation. In this preparation the pulmonary circulation, from right ventricle to left auricle, is left intact, and by means of artificial respiration the lungs are blown up rhythmically so that the blood in its course may take up oxygen and get rid of carbonic acid. The whole systemic circulation is got rid of and replaced by rubber tubes. A glass tube is tied into the largest branch of the aorta, all the other branches being tied, so that the blood driven out by the left ventricle can only escape by the glass tube. From the glass tube a rubber tube passes to a thin rubber tube contained within the wide glass tube. This thin rubber tube can be compressed to any desired extent by pumping air at a known pressure into the glass tube surrounding it. We can thus vary at pleasure the resistance which has to be overcome by the left ventricle and by maintaining a normal pressure in the beginning of the aorta ensure a proper supply of oxygenated blood through the coronary arteries to the muscular tissue of the ventricles.

It is this fact which makes it possible for the warm-blooded heart to continue to beat 8 to 12 hours after removal from the body. On the other side of the artificial resistance the blood is led through a spiral immersed in warm water to keep the blood at body temperature and then passes into a reservoir from which a wide rubber tube leads to a glass glass tube placed in the big vein opening into the right auricle. By means of a screw clip on this tube the inflow of blood may be regulated to any desired extent and can be kept constant while other conditions are varied. Thus in this preparation the three chief factors, temperature, inflow of blood, resistance to the outflow of blood, can be varied separately and at the will of the operator. Any of the heart cavities or any part of the circuit can be connected to manometers so as to record the pressure of the fluid at the different parts of the circuit, and by means of a side tube placed just beyond the artificial resistance we can allow the blood to flow off into a graduated cylinder and thus measure the time taken by the left ventricle to expel 50 or 100 c.cm. of blood, thus measuring the average output of the organ.

An Experiment Described.

A typical experiment may be divided into six stages. Records of one experiment[2] show that in the first stage the heart was beating at a normal rate, 72 per minute, the blood pressure varied from 100 mm. Hg, and the output of the heart was 210 c.cm. of blood per minute. In the second stage the resistance to the flow of blood through the tube was increased to such an extent that the pressure rose to 160 to 180 mm. Hg. The heart continued to beat, and for a time put out just as much blood as it did at the lower pressure. In the third stage the artificial resistance was suddenly reduced to zero, the arterial pressure fell to about 20 mm, Hg, but the heart beat regularly and the outflow of blood was unaltered because the inflow of blood had not been altered. In the fourth stage the inflow of blood was raised suddenly to 600 c.cm. per minute. The heart became bigger, but the regularity of its contractions remained unaltered, and it drove forward all the blood that it received.

The same thing happened in the fifth stage in which the artificial resistance was raised simultaneously with the venous inflow. The reason for these phenomena is that within certain limits the heart isolated from the body can respond to all the demands made upon it; it can overcome a higher resistance, and it can pump out more fluid. In the sixth stage the inflow of blood was further increased to 1200 c.cm. per minute, and the artificial resistance was increased until the blood pressure rose to 200 mm. Hg. This was too much for the heart, which began to beat irregularly and dilated widely. It would have failed altogether if the pressure surrounding the thin rubber tube had not then been released, to allow the artificial pressure to drop to a level at which the left ventricle could empty itself.

If during this experiment the amount of oxygen taken up by the blood had been measured and also the amount of carbonic acid given off by this fluid in passing through the lungs, an increase in both these amounts would judgment it was quite impossible to rest upon their oars or to profess any satisfaction with the state of health in many parts of our Colonies, where the mortality of British subjects was what it was to-day. Indeed, he thought that those by whose efforts and self-sacrifice the results already attained had been won would be the first to acknowledge how comparatively slender was the advantage that we had hitherto gained. He expressed his thanks and the thanks of the Government to a committee presided over by Lord Chalmers, which had recently reported, and which had for its object to inquire into how best to link more closely the problems of research in the Colonies with universities and other allied institutions in this country. More and more forces in different parts of the world were being mobilised in the pursuit of disease. The London and Liverpool Schools of Tropical Medicine in one way or another were doing work in the West Indies and in West Africa. Ceylon, he was told, was in active pursuit of malaria. Mauritius had set aside 10,000,000 rupees, and had been fortunate in enlisting the services of a great medical scientist, Dr. Andrew Balfour, to advise as to how best that money might be applied. In this warfare there were neither national nor racial boundaries. It was with the keenest pleasure that the Colonial Office was able a few weeks ago to welcome the representatives of the International Health Board of the Rockefeller Foundation, who came over from the United States to confer with them as to the possibility of closer coöperation in their beneficent and valuable work, and he had every hope that from these consultations extremely important results would emerge. Wherever they began to tackle the problems of research, or of its application, they were every time confronted with the question of medical personnel. In this matter also his right hon. friend had had the assistance of another strong committee presided over by a very distinguished administrator of ripe experience, Sir Walter Egerton, and of the recommendations made by those gentlemen some had already been adopted, and he hoped as time went on they would be able to make further progress in adopting others. The problem was not an easy one. The unification of a colonial medical service was not easy. In all these matters of administration the Colonial Office was dealing with some 40 to 50 different governments, in an infinite variety of conditions, and infinitely differing in their financial resources, and in these days in nearly all reforms the depth and length of the purse was the deciding factor. He looked to a progressive improvement in the field of human life, which was one of the great fields in which great work remained to be done.

---

[1] [illegible] a lecture delivered at the Royal Institution on [illegible].

[2] Prof. Starling showed on the screen a kinematographic representation of the actual experiment described.

Sir S. HOARE said he agreed with Mr. Wood that medical administration was the most important service of any of our tropical administrations. On making inquiry into medical administration in the West Indies and comparing it with what the Americans had done in Panama, or with, indeed, what they had done in a lesser degree in countries like Guatemala, he was afraid they would find that our medical administration had lagged behind. He wished to see a High Commissioner go to the West Indies.

Lieut.-Colonel FREMANTLE said that physical health was the greatest essential in the development of the Colonies of our vast Empire. Therefore he warmly welcomed the statement of the Under-Secretary as the most satisfactory that had ever been made to the House. It was full of hope, but there was need for a great deal of backing, and he did not feel at all satisfied that the good intentions would be carried into effect. It was essential to see that medical service throughout the Empire was more efficiently run. The need for this was originally put forward by Joseph Chamberlain when he was Secretary of State for the Colonies, and his grant to the School of Tropical Medicine was the first public recognition by the Government of the need of this work. The school had prospered, but he would like to bring the Committee face to face with the point of view of the non-medical men who were engaged in the Colonial Service themselves, and who saw how any deficiency in the medical service affected them. They felt a grievance that officers who joined the Service on the understanding that their medical attention was going to be provided found themselves, after many years of service, at a distance of perhaps 50, or 100, or 200, or even 300 miles in the bush away from a medical officer, not because he could not be provided, but because at the present time there was a deficiency of medical officers which was not being made good. Their aim should be to raise the somewhat out of the way colonies to such a stage by bachelor development that men could safely take out their womenfolk and their children. In order to do that they must supply proper medical attendance. The position could be best summed up in a letter from one resident to another, from which he quoted the following:—

"During the war there was an excuse for the shortage of medical officers, but now there appears to be an absolute indifference on the part of the Colonial Office, and no attempt is made to fill the vacancies. The neglect of the enormous amount of work to be done is very disheartening, and the men out there can only touch the fringe of their work. I stopped at one place and found a sufficient number of cases to keep a man going for a fortnight. I wish you would all send in a united protest. Medical attention is promised on appointment, and this should be shouted from the housetops."

The matter had been taken up by the Colonial Office, and he had asked for a definite return which the Under-Secretary supplied on July 4th as regards the deficiencies in the Service. It dealt with all the different services, and showed a deficiency of 114 vacancies on a strength of about 600. On the West African Medical Staff the total strength was 152, a deficiency of 68 on July 1st: it did not include 15 natives not attached to the medical staff and four dentists who were also excluded. That was a serious shortage, and exemplified all other countries. The complaints were even worse in some of the smaller colonies. In many cases there was held out to the medical officer the promise of private practice, and he was paid some £300 or £400 to do special Government duty. That was a misleading arrangement which had proved to be ineffective, because if there was any private practice the medical officer gave it as much time as possible and as little as possible to his Government duties. In many instances there was no real private practice, and there had been two or three cases where men, feeling that they had been misled, returned home. The official attitude was that some of the recommendations of the Departmental Committee had been granted and others might be granted. That was very vague, and he should like some more definite assurance. The pay in the West African Medical Service had been improved, but it was still glaringly insufficient. He contended that they should build up a medical service for the whole of the Colonies and that it should be under the Government. Members should have a good initial salary and a proper chance to get work. They should be entitled to pensions and gratuities, together with free passages for their families. He again protested against the way in which these things were considered in watertight compartments as different services of the Crown. The Departmental Committee had again pressed for some consideration to be given to the possibility of a United Government Medical Service, with definite terms of service. If this could be brought about it would effect an enormous saving, and it would help imperial development a thousand fold.

Mr. CHURCHILL (Secretary of State for the Colonies), replying to points raised in the debate, said that he agreed with Mr. Wood that great as had been the progress that they had seen in the last 20 years they had only just begun to assert and establish the mastery of science over the jungle of diseases. He had been told of a method of destroying the larvæ of a particular mosquito by means of cows. The mosquito laid its eggs in the protecting grasses at the very edge of the water and stretched out into the water, and in this position it was protected from the depredations of a small fish which otherwise devoured it with avidity. But on the introduction of the cow into the area the grass was cropped and nibbled close to the water's edge, and the fish immediately attacked the larvæ. He could not guarantee the exact scientific accuracy of the illustration, but it served as an example of the kind of warfare which was being waged with an increasing measure of success.

On a division the motion to reduce the vote was negatived by 123 votes to 43, and the vote was then agreed to.

Aggravated Disability Cases.

Mr. CAPE asked the Minister of Pensions what was the number of pensions originally awarded as attributable to war service which had, during the 12 months ended June 30th this year, been altered to aggravated, and the number of pensions assessed as aggravated which had been altered to aggravation passed away.—Mr. MACPHERSON replied: I regret that I am unable to give the desired figures, but my hon. friend will, perhaps, be interested to learn that a recent test made for a period of seven weeks showed that less than 2 per cent. of the cases dealt with are changed on re-boarding from "attributable" to "aggravated."

Commissioners of Medical Services and Temporary Grants.

Lieut.-Colonel HURST asked the Minister of Pensions whether he was aware that the provision in the local committee's handbook enabling committees to give temporary grants pending awards by appeals tribunals was practically a dead letter in consequence of the failure on the part of the Commissioners of Medical Services to notify the result of the medical boards to the committees, which was a condition precedent to any such grants; whether he was aware that in only 6 of the 300 Manchester cases now awaiting hearing by the appeals tribunals had such notifications been made; and whether he would take steps to redress this grievance.—Mr. MACPHERSON replied: I would remind my hon. and gallant friend that advances in these cases are only permissible if the board find in the man's favour, and I have no information to show that the dogs were employed in a lively scene of carnage, which will do much to compensate for the suggestion of education so resented by many frequenters of the kinema. Briefly, the film is a good one, carefully thought out, and cleverly staged; it should be of much value in arousing interest in the rat problem. After its termination Lord Aberconway appealed on behalf of the Vermin Repression Society for a sum of £10,000, which he described as a good investment for business men. Both he and Mr. Alfred E. Moore, hon. secretary of the Society, emphasised the need of a cordon of rat panels throughout the country, in order to prevent a "rat week" in one neighbourhood necessitating a similar task in adjacent districts shortly afterwards. Mr. Moore also strongly deprecated the action of certain local authorities in dispersing with the services of officers appointed for the destruction of rats.

A CITIZEN OF EMPIRE.

THE appointment of an assistant medical officer to the Swaffield-road Institution and Intermediate Schools was before the Wandsworth Board of Guardians last week, when Mr. Hormazd Ardeshir Topalia, an Indian, was appointed by a preponderating majority of votes. "Would you take it as an insult if I called you a foreigner?" a guardian asked, when Mr. Topalia replied: "Most certainly I should." It was the right answer, and we are glad it was given.

APPROVED SALVARSAN SUBSTITUTES.

IN THE LANCET of May 21st (p. 1112) we published a list of those drugs which are approved by the Ministry of Health as substitutes for salvarsan, and may be supplied free of charge by local authorities to medical practitioners. This list was issued in Circular 166, which is now superseded by a new official list (List 13) dated June, 1921. The new list includes the five drugs noted by us on May 21st at the same price and dosage, and in addition:—

Arsenobenzol (Cerbiere, Modern Pharmacals, Ltd.), in doses of 0·1–0·6 g. (costing *1s.* to *5s.*). Novarsenobenzol (Cerbiere, Modern Pharmacals, Ltd.), in doses of 0·15–0·90 g. (costing *9d.* to *4s. 6d.*).

GLASS-BLOWING.

THE ability to make one's own apparatus for use in the laboratory is an accomplishment of the utmost utility. Early instruction is needed from a teacher, but with care and patient application there is little difficulty in acquiring, at any rate for the construction of the more commonly used appliances, the necessary skill by means of a text-book, and a little treatise by Mr. Bernard D. Bolas entitled "Glass-Blowing"[1] is well adapted to the purpose. The various operations are clearly described, and the reasons for failure in producing satisfactory results are indicated, while instructions are also given in drilling, grinding, filing, and other necessary manipulations connected with the use of working in glass. Notes on various kinds of blow-pipes and lamps, and the utilisation of glass scraps add to the value of a very practical little manual.

A COLLEGE FOR BLIND GIRLS.

To the Editor of THE LANCET.

SIR,—May I be allowed through your columns to draw attention to the new college for the higher education of blind girls which has recently been opened under the auspices of the National Institute for the Blind. The college is situated at Chorley Wood, on the foothills of the Chilterns, some 20 miles from London by road and rail. The building is a fine old mansion, standing on high ground on the south border of the wide and beautiful heath which tops that piece of country. The spaciousness of the house, the spread of the grounds, with the splendid trees therein, and the sense of openness which the position affords, together make it a place of exceptional interest for a school of this order. It would be difficult to find a place where other senses than sight received so many and such happy impressions.

The college is for the higher education of girls who are totally blind or have no useful degree of sight. The education will be as liberal as in the best public schools for girls, and the physical and mental development afforded will enable blind girls to live full and active lives at school, at home, and in professions. The principal is Miss Phyllis Monk, M.A., formerly of Girton College, Cambridge, and latterly a mistress of Roedean School, Brighton; with her is associated an efficient teaching and house staff.

I have visited the school myself, and can speak of the excellence of the arrangements for teaching and for the comfort of the girls; also on my visit there accompanied me a lady experienced in domestic affairs, and she was greatly impressed with the domestic arrangements and the evident happiness of the resident pupils. The fees for a place of this order are moderate, and there are some scholarships for girls of promise. There are, happily, not many blind girls of our class, but for these few there can be no better place of education and training than this new college. Saturday, July 23rd, will be visitors' day. Miss Monk will be pleased to receive doctors and others interested during the afternoon of that day. The address is "The Cedars," Chorley Wood, Herts. The school is about ten minutes' walk from the station across the heath; the London-road passes within a hundred yards of the school.

I am, Sir, yours faithfully,

London, W., July 16th, 1921. N. BISHOP HARMAN.

CHOLERA IN ASSAM.

THE Secretary for India was recently asked in the House of Commons whether he was aware that large numbers of coolies engaged in tea-gardens in Assam were lately induced by agitators to desert to their homes, and whether many of these deserting coolies died on their way to their homes from disease and privation. Mr. Montagu circulated in reply a full summary of two communiqués published by the Governments of Assam and Bengal. From these communiqués it appeared that the coolies struck work on May 22nd; disaffection spread, and by the middle of the month between 6000 and 7000 coolies had left the gardens. Food was provided by the Government for those who needed it, and one issue of rice was accepted; but the coolies were then led to believe that acceptance of food thus supplied entailed their being sent back to the gardens. Government provision was made for the sick and destitute women, children, and aged. By May 19th about 3000 coolies had collected in and around the station yard at Chandpur; these premises rapidly became grossly insanitary, and cholera broke out amongst the coolies themselves and also amongst the station staff. Persuasion having failed to move the coolies they were dispersed by force; apparently many of them scattered through the town, remaining there as a great source of danger to the population. Dr. Batra, of the Health Department, made full arrangements for dealing with the sanitary and medical situation, but was much hampered by the non-coöperation of the men's leaders, who professed their inability to transfer some 500 of the men left in Chandpur to certain disused jute godowns, where about a thousand had been collected. Dr. Batra was unable to buy milk, vegetables, and other necessaries without the signature of the local leaders; finally he was compelled to withdraw with his assistants from his extemporised hospital, but remained in the town in readiness to render any assistance in his power. His estimate of the deaths from cholera during the latter part of May was 160 at the lowest figure.

A CONGRESS is shortly to be held in Vienna at which the international aspect of child welfare will be discussed by a number of distinguished men and women from various countries, including Prof. Pirquet, Mrs. Jane Adams, Miss Edith Pye, Miss Kathleen Courtney, and Dr. Hilda Clark.

B. Burjorjee.—Our correspondent does not give his complete address. The only translation of Prof. I. Boas's Diagnostik und Therapie der Magenkrankheiten of which we know is one by A. Bernheim, published by F. A. Davis Company, Philadelphia, in 1907, at 25s. The latest German edition was reviewed in THE LANCET of May 21st, 1921.

Professional Advertisement.—Our correspondent, who does not entrust us with his name, is reflecting on the professional standards of foreigners, and cannot be certain that the institutions from which they derive their degrees and diplomas will have no objection to the advertisement. This might not be the case with British practitioners.

THE LANCET: SUBSCRIPTION RATES.

		£	s.	d.
INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6
ABROAD	One Year	£2	10	0
